Note by Turkey: The information in this document with reference to “Cyprus” relates to the southern part of the Island. There is no single authority representing both Turkish and Greek Cypriot people on the Island. Turkey recognises the Turkish Republic of Northern Cyprus (TRNC). Until a lasting and equitable solution is found within the context of the United Nations, Turkey shall preserve its position concerning the “Cyprus issue”.

Note by all the European Union Member States of the OECD and the European Union: The Republic of Cyprus is recognised by all members of the United Nations with the exception of Turkey. The information in this document relates to the area under the effective control of the Government of the Republic of Cyprus.

The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law.

Foreword

Equipping citizens with the skills necessary to achieve their full potential, participate in an increasingly interconnected global economy, and ultimately convert better jobs into better lives is a central preoccupation of policy makers around the world. Results from the OECD's recent Survey of Adult Skills show that highly skilled adults are twice as likely to be employed and almost three times more likely to earn an above-median salary than poorly skilled adults. In other words, poor skills severely limit people's access to better-paying and more rewarding jobs. Highly skilled people are also more likely to volunteer, see themselves as actors rather than as objects of political processes, and are more likely to trust others. Fairness, integrity and inclusiveness in public policy thus all hinge on the skills of citizens.

The ongoing economic crisis has only increased the urgency of investing in the acquisition and development of citizens' skills – both through the education system and in the workplace. At a time when public budgets are tight and there is little room for further monetary and fiscal stimulus, investing in structural reforms to boost productivity, such as education and skills development, is key to future growth. Indeed, investment in these areas is essential to support the recovery, as well as to address long-standing issues such as youth unemployment and gender inequality.

In this context, more and more countries are looking beyond their own borders for evidence of the most successful and efficient policies and practices. Indeed, in a global economy, success is no longer measured against national standards alone, but against the best-performing and most rapidly improving education systems. Over the past decade, the OECD Programme for International Student Assessment, PISA, has become the world's premier yardstick for evaluating the quality, equity and efficiency of school systems. But the evidence base that PISA has produced goes well beyond statistical benchmarking. By identifying the characteristics of high-performing education systems PISA allows governments and educators to identify effective policies that they can then adapt to their local contexts.

The results from the PISA 2012 assessment, which was conducted at a time when many of the 65 participating countries and economies were grappling with the effects of the crisis, reveal wide differences in education outcomes, both within and across countries. Using the data collected in previous PISA rounds, we have been able to track the evolution of student performance over time and across subjects. Of the 64 countries and economies with comparable data, 40 improved their average performance in at least one subject. Top performers such as Shanghai in China or Singapore were able to further extend their lead, while countries like Brazil, Mexico, Tunisia and Turkey achieved major improvements from previously low levels of performance.

Some education systems have demonstrated that it is possible to secure strong and equitable learning outcomes at the same time as achieving rapid improvements. Of the 13 countries and economies that significantly improved their mathematics performance between 2003 and 2012, three also show improvements in equity in education during the same period, and another nine improved their performance while maintaining an already high level of equity – proving that countries do not have to sacrifice high performance to achieve equity in education opportunities.

Nonetheless, PISA 2012 results show wide differences between countries in mathematics performance. The equivalent of almost six years of schooling, 245 score points, separates the highest and lowest average performances

of the countries that took part in the PISA 2012 mathematics assessment. The difference in mathematics performances within countries is even greater, with over 300 points – the equivalent of more than seven years of schooling – often separating the highest- and the lowest-achieving students in a country. Clearly, all countries and economies have excellent students, but few have enabled all students to excel.

The report also reveals worrying gender differences in students' attitudes towards mathematics: even when girls perform as well as boys in mathematics, they report less perseverance, less motivation to learn mathematics, less belief in their own mathematics skills, and higher levels of anxiety about mathematics. While the average girl underperforms in mathematics compared with the average boy, the gender gap in favour of boys is even wider among the highest-achieving students. These findings have serious implications not only for higher education, where young women are already under-represented in the science, technology, engineering and mathematics fields of study, but also later on, when these young women enter the labour market. This confirms the findings of the OECD Gender Strategy, which identifies some of the factors that create – and widen – the gender gap in education, labour and entrepreneurship. Supporting girls' positive attitudes towards and investment in learning mathematics will go a long way towards narrowing this gap.

PISA 2012 also finds that the highest-performing school systems are those that allocate educational resources more equitably among advantaged and disadvantaged schools and that grant more autonomy over curricula and assessments to individual schools. A belief that all students can achieve at a high level and a willingness to engage all stakeholders in education – including students, through such channels as seeking student feedback on teaching practices – are hallmarks of successful school systems.

PISA is not only an accurate indicator of students' abilities to participate fully in society after compulsory school, but also a powerful tool that countries and economies can use to fine-tune their education policies. There is no single combination of policies and practices that will work for everyone, everywhere. Every country has room for improvement, even the top performers. That's why the OECD produces this triennial report on the state of education across the globe: to share evidence of the best policies and practices and to offer our timely and targeted support to help countries provide the best education possible for all of their students. With high levels of youth unemployment, rising inequality, a significant gender gap, and an urgent need to boost growth in many countries, we have no time to lose. The OECD stands ready to support policy makers in this challenging and crucial endeavour.

Angel Gurría
OECD Secretary-General

Acknowledgements

This report is the product of a collaborative effort between the countries participating in PISA, the experts and institutions working within the framework of the PISA Consortium, and the OECD Secretariat. The report was drafted by Andreas Schleicher, Francesco Avvisati, Francesca Borgonovi, Miyako Ikeda, Hiromichi Katayama, Flore-Anne Messy, Chiara Monticone, Guillermo Montt, Sophie Vayssettes and Pablo Zoido of the OECD Directorate for Education and Skills and the Directorate for Financial Affairs, with statistical support from Simone Bloem and Giannina Rech and editorial oversight by Marilyn Achiron. Additional analytical and editorial support was provided by Adele Atkinson, Jonas Bertling, Marika Boiron, Célia Braga-Schich, Tracey Burns, Michael Davidson, Cassandra Davis, Elizabeth Del Bourgo, John A. Dossey, Joachim Funke, Samuel Greiff, Tue Halgreen, Ben Jensen, Eckhard Klieme, André Laboul, Henry Levin, Juliette Mendelovits, Tadakazu Miki, Christian Monseur, Simon Normandeau, Mathilde Overduin, Elodie Pools, Dara Ramalingam, William H. Schmidt (whose work was supported by the Thomas J. Alexander fellowship programme), Kaye Stacey, Lazar Stankov, Ross Turner, Elisabeth Villoutreix and Allan Wigfield. The system-level data collection was conducted by the OECD NESLI (INES Network for the Collection and Adjudication of System-Level Descriptive Information on Educational Structures, Policies and Practices) team: Bonifacio Agapin, Estelle Herbaut and Jean Yip. Volume II also draws on the analytic work undertaken by Jaap Scheerens and Douglas Willms in the context of PISA 2000. Administrative support was provided by Claire Chetcuti, Juliet Evans, Jennah Huxley and Diana Tramontano.

The OECD contracted the Australian Council for Educational Research (ACER) to manage the development of the mathematics, problem solving and financial literacy frameworks for PISA 2012. Achieve was also contracted by the OECD to develop the mathematics framework with ACER. The expert group that guided the preparation of the mathematics assessment framework and instruments was chaired by Kaye Stacey; Joachim Funke chaired the expert group that guided the preparation of the problem-solving assessment framework and instruments; and Annamaria Lusardi led the expert group that guided the preparation of the financial literacy assessment framework and instruments. The PISA assessment instruments and the data underlying the report were prepared by the PISA Consortium, under the direction of Raymond Adams at ACER.

The development of the report was steered by the PISA Governing Board, which is chaired by Lorna Bertrand (United Kingdom), with Benő Csapó (Hungary), Daniel McGrath (United States) and Ryo Watanabe (Japan) as vice chairs. Annex C of the volumes lists the members of the various PISA bodies, as well as the individual experts and consultants who have contributed to this report and to PISA in general.

Table of Contents

EXECUTIVE SUMMARY	13
READER'S GUIDE	17
WHAT IS PISA?	19
CHAPTER 1 DEFINING AND MEASURING EQUITY IN EDUCATION	25
How PISA examines equity in education opportunities	28
▪ The quantity and quality of educational resources	28
▪ Instructional content and practices	29
▪ Combining better performance with greater equity	29
Examining equity throughout this report	30
CHAPTER 2 EQUITY IN OUTCOMES	33
Performance and socio-economic status across school systems	34
▪ Disparities in performance related to socio-economic status	38
▪ Resilient students	40
▪ Mean performance, after taking account of socio-economic status	40
▪ Between-school variation in performance	44
▪ Performance differences across schools and socio-economic disparities	46
Providing access to schooling to all 15-year-olds	53
Trends in equity between PISA 2003 and PISA 2012	56
▪ Trends in the profile and distribution of students in schools	59
CHAPTER 3 THE CHALLENGE OF DIVERSITY	63
Family structure and student performance	64
Parents' job status: Targeting education policies through social policy for the unemployed	66
School location and variation in performance across geographical areas	69
Equity in outcomes for immigrant students	71
▪ The impact of other social policies on the profile of immigrant students	72
▪ High levels of performance across a diverse student population	72
▪ Higher levels of performance among an increasingly diverse student population	74
▪ Language minorities among immigrant students	79
▪ First- and second-generation students	80
▪ The "late-arrival penalty"	80
Concentration of disadvantage	82
Performance, immigrant status and country of origin	84
CHAPTER 4 EQUITY IN OPPORTUNITIES TO LEARN AND IN RESOURCES	87
Disparities in exposure to formal mathematics, socio-economic status and performance	90
▪ Disparities within countries	91
▪ Differences in exposure to mathematics and average mathematics performance across school systems	91
▪ Between-school differences in opportunity to learn, socio-economic status and performance	91

Equity in educational resources	93
▪ More is not always better.....	95
▪ Challenging school environments.....	95
▪ Learning opportunities outside school and parents' expectations of schools.....	95
Opportunities, resources, performance and socio-economic status	98
Participation in pre-primary education	99
 CHAPTER 5 POLICY IMPLICATIONS OF EQUITY IN EDUCATION	103
Patterns in the relationship between performance and socio-economic status	105
A disproportionate number of low-performing students	111
Different slopes and strengths of socio-economic gradients	111
▪ Universal policies for countries where performance differences are small and there is a weak relationship between performance and socio-economic status.....	112
▪ Policies that target socio-economic disadvantage for those countries where there are small performance differences and a strong relationship between performance and socio-economic status.....	114
▪ Policies that target both performance and socio-economic disadvantage for countries where there are large performance differences and a strong relationship between performance and socio-economic status.....	115
Large socio-economic disparities	117
Targeting low-performing and socio-economically disadvantaged schools	119
Targeting students within schools	122
 ANNEX A PISA 2012 TECHNICAL BACKGROUND	129
Annex A1 Construction of mathematics scales and indices from the student, school and parent context questionnaires.....	130
Annex A2 The PISA target population, the PISA samples and the definition of schools.....	146
Annex A3 Technical notes on analyses in this volume.....	158
Annex A4 Quality assurance.....	162
Annex A5 Technical details of trends analyses.....	163
 ANNEX B PISA 2012 DATA	173
Annex B1 Results for countries and economies.....	174
Annex B2 Results for regions within countries.....	281
Annex B3 List of tables available on line.....	326
 ANNEX C THE DEVELOPMENT AND IMPLEMENTATION OF PISA – A COLLABORATIVE EFFORT	327

BOXES

Box II.1.1.	What do the PISA scores mean?	28

Executive Summary

PISA defines equity in education as providing all students, regardless of gender, family background or socio-economic status, with opportunities to benefit from education. Defined in this way, equity does not imply that everyone should have the same results. It does mean, however, that students' socio-economic status or the fact that they have an immigrant background has little or no impact on their performance, and that all students, regardless of their background, are offered access to quality educational resources and opportunities to learn.

Of the 39 countries and economies that participated in both PISA 2003 and 2012, Mexico, Turkey and Germany improved both their mathematics performance and their levels of equity in education during the period.

These three countries improved both equity and performance either by reducing the extent to which students' socio-economic background predicts their mathematics performance or by reducing the average difference in performance between advantaged and disadvantaged students. Nine additional countries and economies improved their average performance between 2003 and 2012 while maintaining their equity levels.

Australia, Canada, Estonia, Finland, Hong Kong-China, Japan, Korea, Liechtenstein and Macao-China achieve high levels of performance and equity in education opportunities as assessed in PISA 2012.

Equity in education opportunities is average in 12 countries and economies and below average in two of the 23 countries and economies that perform above the OECD average in mathematics. In all countries and economies that participated in PISA 2012, a student's socio-economic status has a strong impact on his or her performance. Across OECD countries, 15% of the variation in student performance in mathematics is attributed to differences in students' socio-economic status. Among high-performing countries, this proportion ranges from 3% in Macao-China to 18% in New Zealand. In contrast, in Bulgaria, Chile, France, Hungary, Peru, the Slovak Republic and Uruguay more than 20% of the difference in student performance can be attributed to students' socio-economic status.

Across OECD countries, a more socio-economically advantaged student scores 39 points higher in mathematics – the equivalent of nearly one year of schooling – than a less-advantaged student.

Among the 23 highest-performing countries and economies, performance differences related to socio-economic status are narrower-than-average in Canada, Estonia, Finland, Hong Kong-China, Macao-China and Viet Nam, about average in 11 countries and economies, and wider-than-average in 6. Striking performance differences are also observed between students in advantaged schools and those in disadvantaged schools: students attending socio-economically advantaged schools outscore those in disadvantaged schools by more than 104 points in mathematics, on average across OECD countries.

Across OECD countries 6% of the entire student population are “resilient”, meaning that they beat the socio-economic odds against them and exceed expectations, when compared with students in other countries.

In Hong Kong-China, Korea, Macao-China, Shanghai-China, Singapore and Viet Nam 13% or more of the overall student population are resilient and perform among the top 25% across all participating countries after taking socio-economic status into account. Between 2003 and 2012, the share of resilient students increased in Germany, Italy, Poland, Tunisia and Turkey.

The share of immigrant students in OECD countries increased from 9% in 2003 to 12% in 2012 while the difference in mathematics performance between immigrant and non-immigrant students shrank by 11 score points during the same period.

Immigrant students tend to be socio-economically disadvantaged in comparison to non-immigrant students, yet even when comparing students of similar socio-economic status, immigrant students perform worse in mathematics than non-immigrant students. In 2012, they scored an average of 33 points lower in mathematics than non-immigrant students before accounting for socio-economic status, and an average of 21 points lower after accounting for socio-economic status. In Canada, Ireland, Israel, New Zealand and the United Kingdom, however, immigrant and non-immigrant students perform equally well.

The concentration of immigrant students in a school is not, in itself, associated with poor performance.

In general, immigrant students and those who do not speak the language of assessment at home tend to be concentrated in disadvantaged schools. In the United States, for example, 40% of students in disadvantaged schools are immigrants, whereas 13% of students in advantaged schools are. Across OECD countries, students who attend schools where more than one in four students are immigrants tend to perform worse than those in schools with no immigrant students. However, the 19 score-point difference between the two groups is more than halved – to 8 points – after the socio-economic status of the students and schools is taken into account. Belgium, Estonia, Greece, Mexico and Portugal are the only countries where there are performance differences of 20 score points or more between the two groups, after accounting for socio-economic status.

Across OECD countries, students who reported that they had attended pre-primary school for more than one year score 53 points higher in mathematics – the equivalent of more than one years of schooling – than students who had not attended pre-primary education.

In all but two countries with available data, students who had attended pre-primary education for more than one year outperformed students who had not, after taking socio-economic status into account. This finding remains unchanged even after socio-economic status is accounted for, except in Croatia, Estonia, Ireland, Korea, Latvia, Slovenia and the United States.

OECD countries allocate at least an equal, if not a larger, number of mathematics teachers to socio-economically disadvantaged schools as to advantaged schools; but disadvantaged schools tend to have great difficulty in attracting qualified teachers.

In the Netherlands, the proportion of qualified teachers in advantaged schools (52%) is three times larger than the proportion of qualified teachers in disadvantaged schools (14%), while the student-teacher ratio is 28% higher in advantaged schools than it is in disadvantaged schools (18 students compared with 14 students per teacher, respectively).

Reader's Guide

Data underlying the figures

The data referred to in this volume are presented in Annex B and, in greater detail, including some additional tables, on the PISA website (www.pisa.oecd.org).

Four symbols are used to denote missing data:

- a The category does not apply in the country concerned. Data are therefore missing.
- c There are too few observations or no observation to provide reliable estimates (i.e. there are fewer than 30 students or fewer than 5 schools with valid data).
- m Data are not available. These data were not submitted by the country or were collected but subsequently removed from the publication for technical reasons.
- w Data have been withdrawn or have not been collected at the request of the country concerned.

Country coverage

This publication features data on 65 countries and economies, including all 34 OECD countries and 31 partner countries and economies (see map in the section *What is PISA?*).

The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law.

Two notes were added to the statistical data related to Cyprus:

1. Note by Turkey: The information in this document with reference to “Cyprus” relates to the southern part of the Island. There is no single authority representing both Turkish and Greek Cypriot people on the Island. Turkey recognises the Turkish Republic of Northern Cyprus (TRNC). Until a lasting and equitable solution is found within the context of the United Nations, Turkey shall preserve its position concerning the “Cyprus issue”.
2. Note by all the European Union Member States of the OECD and the European Union: The Republic of Cyprus is recognised by all members of the United Nations with the exception of Turkey. The information in this document relates to the area under the effective control of the Government of the Republic of Cyprus.

Calculating international averages

An OECD average corresponding to the arithmetic mean of the respective country estimates was calculated for most indicators presented in this report. The OECD average is used to compare performance across school systems. In the case of some countries, data may not be available for specific indicators, or specific categories may not apply. Readers should, therefore, keep in mind that the term “OECD average” refers to the OECD countries included in the respective comparisons.

Rounding figures

Because of rounding, some figures in tables may not exactly add up to the totals. Totals, differences and averages are always calculated on the basis of exact numbers and are rounded only after calculation.

All standard errors in this publication have been rounded to one or two decimal places. Where the value 0.0 or 0.00 is shown, this does not imply that the standard error is zero, but that it is smaller than 0.05 or 0.005, respectively.

Reporting student data

The report uses “15-year-olds” as shorthand for the PISA target population. PISA covers students who are aged between 15 years 3 months and 16 years 2 months at the time of assessment and who are enrolled in school and have completed at least 6 years of formal schooling, regardless of the type of institution in which they are enrolled and of whether they are in full-time or part-time education, of whether they attend academic or vocational programmes, and of whether they attend public or private schools or foreign schools within the country.

Reporting school data

The principals of the schools in which students were assessed provided information on their schools’ characteristics by completing a school questionnaire. Where responses from school principals are presented in this publication, they are weighted so that they are proportionate to the number of 15-year-olds enrolled in the school.

Focusing on statistically significant differences

This volume discusses only statistically significant differences or changes. These are denoted in darker colours in figures and in bold font in tables. See Annex A3 for further information.

Abbreviations used in this report

ESCS	PISA index of economic, social and cultural status	PPP	Purchasing power parity
GDP	Gross domestic product	S.D.	Standard deviation
ISCED	International Standard Classification of Education	S.E.	Standard error
ISCO	International Standard Classification of Occupations	STEM	Science, Technology, Engineering and Mathematics

Further documentation

For further information on the PISA assessment instruments and the methods used in PISA, see the *PISA 2012 Technical Report* (OECD, forthcoming). The reader should note that there are gaps in the numbering of tables because some tables appear on line only and are not included in this publication. To consult the set of web-only data tables, visit the PISA website (www.pisa.oecd.org).

This report uses the OECD StatLinks service. Below each table and chart is a url leading to a corresponding Excel™ workbook containing the underlying data. These urls are stable and will remain unchanged over time. In addition, readers of the e-books will be able to click directly on these links and the workbook will open in a separate window, if their internet browser is open and running.

What is PISA?

“What is important for citizens to know and be able to do?” That is the question that underlies the triennial survey of 15-year-old students around the world known as the Programme for International Student Assessment (PISA). PISA assesses the extent to which students near the end of compulsory education have acquired key knowledge and skills that are essential for full participation in modern societies. The assessment, which focuses on reading, mathematics, science and problem solving, does not just ascertain whether students can reproduce knowledge; it also examines how well students can extrapolate from what they have learned and apply that knowledge in unfamiliar settings, both in and outside of school. This approach reflects the fact that modern economies reward individuals not for what they know, but for what they can do with what they know.

PISA is an ongoing programme that offers insights for education policy and practice, and that helps monitor trends in students’ acquisition of knowledge and skills across countries and economies and in different demographic subgroups within each country. PISA results reveal what is possible in education by showing what students in the highest-performing and most rapidly improving school systems can do. The findings allow policy makers around the world to gauge the knowledge and skills of students in their own countries in comparison with those in other countries, set policy targets against measurable goals achieved by other school systems, and learn from policies and practices applied elsewhere. While PISA cannot identify cause-and-effect relationships between policies/practices and student outcomes, it can show educators, policy makers and the interested public how education systems are similar and different – and what that means for students.

A test the whole world can take

PISA is now used as an assessment tool in many regions around the world. It was implemented in 43 countries and economies in the first assessment (32 in 2000 and 11 in 2002), 41 in the second assessment (2003), 57 in the third assessment (2006) and 75 in the fourth assessment (65 in 2009 and 10 in 2010). So far, 65 countries and economies have participated in PISA 2012.

In addition to OECD member countries, the survey has been or is being conducted in:

East, South and Southeast Asia: Himachal Pradesh-India, Hong Kong-China, Indonesia, Macao-China, Malaysia, Shanghai-China, Singapore, Chinese Taipei, Tamil Nadu-India, Thailand and Viet Nam.

Central, Mediterranean and Eastern Europe, and Central Asia: Albania, Azerbaijan, Bulgaria, Croatia, Georgia, Kazakhstan, Kyrgyzstan, Latvia, Liechtenstein, Lithuania, the former Yugoslav Republic of Macedonia, Malta, Moldova, Montenegro, Romania, the Russian Federation and Serbia.

The Middle East: Jordan, Qatar and the United Arab Emirates.

Central and South America: Argentina, Brazil, Colombia, Costa Rica, Netherlands-Antilles, Panama, Peru, Trinidad and Tobago, Uruguay and Miranda-Venezuela.

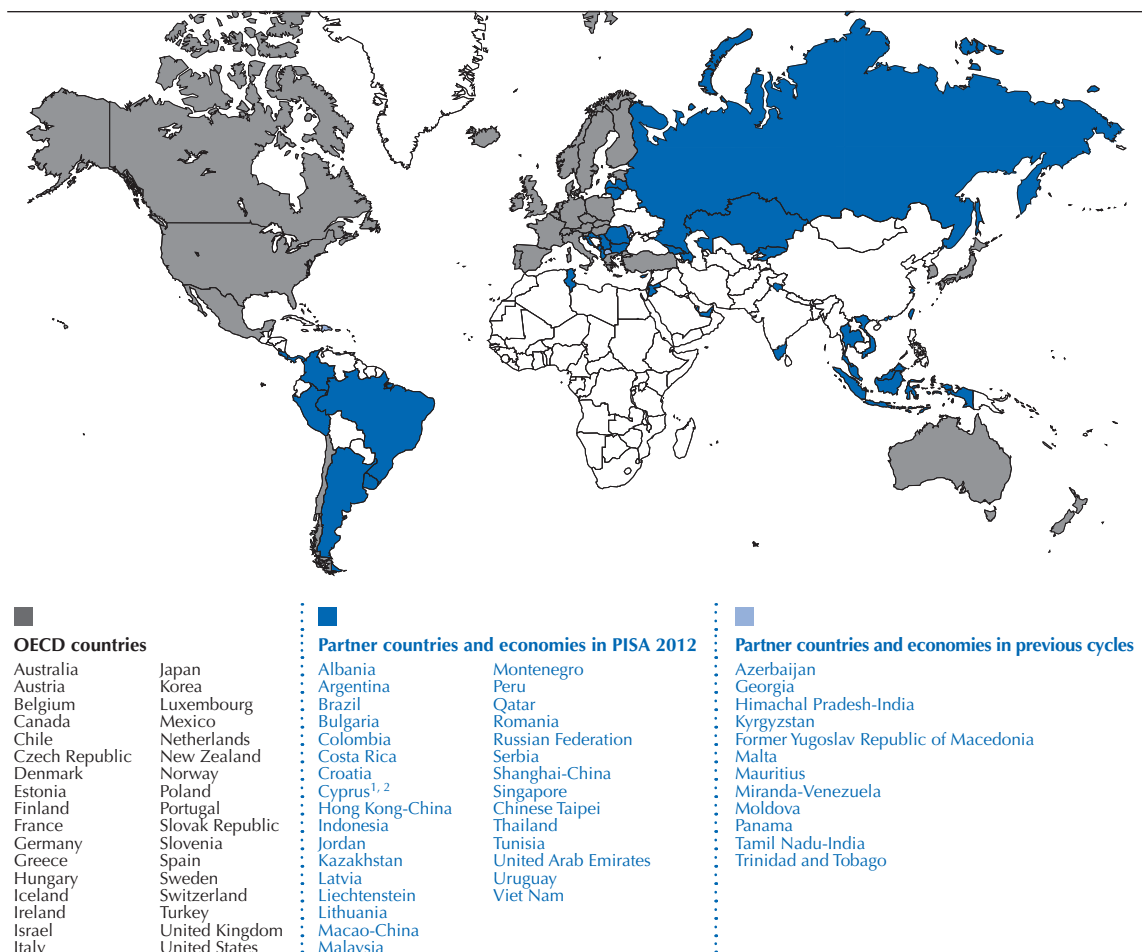

Africa: Mauritius and Tunisia.

Decisions about the scope and nature of the PISA assessments and the background information to be collected are made by participating countries based on recommendations from leading experts. Considerable efforts and resources are devoted to achieving cultural and linguistic breadth and balance in assessment materials. Since the design and translation of the test, as well as sampling and data collection, are subject to strict quality controls, PISA findings are considered to be highly valid and reliable.

...

Map of PISA countries and economies

1. Note by Turkey: The information in this document with reference to "Cyprus" relates to the southern part of the Island. There is no single authority representing both Turkish and Greek Cypriot people on the Island. Turkey recognises the Turkish Republic of Northern Cyprus (TRNC). Until a lasting and equitable solution is found within the context of the United Nations, Turkey shall preserve its position concerning the "Cyprus issue".

2. Note by all the European Union Member States of the OECD and the European Union: The Republic of Cyprus is recognised by all members of the United Nations with the exception of Turkey. The information in this document relates to the area under the effective control of the Government of the Republic of Cyprus.

PISA's unique features include its:

- policy orientation, which links data on student learning outcomes with data on students' backgrounds and attitudes towards learning and on key factors that shape their learning, in and outside of school, in order to highlight differences in performance and identify the characteristics of students, schools and school systems that perform well;
- innovative concept of "literacy", which refers to students' capacity to apply knowledge and skills in key subjects, and to analyse, reason and communicate effectively as they identify, interpret and solve problems in a variety of situations;
- relevance to lifelong learning, as PISA asks students to report on their motivation to learn, their beliefs about themselves, and their learning strategies;
- regularity, which enables countries and economies to monitor their progress in meeting key learning objectives; and
- breadth of coverage, which, in PISA 2012, encompasses the 34 OECD member countries and 31 partner countries and economies.

Key features of PISA 2012

The content

- The PISA 2012 survey focused on mathematics, with reading, science and problem solving as minor areas of assessment. For the first time, PISA 2012 also included an assessment of the financial literacy of young people, which was optional for countries and economies.
- PISA assesses not only whether students can reproduce knowledge, but also whether they can extrapolate from what they have learned and apply their knowledge in new situations. It emphasises the mastery of processes, the understanding of concepts, and the ability to function in various types of situations.

The students

- Around 510 000 students completed the assessment in 2012, representing about 28 million 15-year-olds in the schools of the 65 participating countries and economies.

The assessment

- Paper-based tests were used, with assessments lasting a total of two hours for each student. In a range of countries and economies, an additional 40 minutes were devoted to the computer-based assessment of mathematics, reading and problem solving.
- Test items were a mixture of multiple-choice items and questions requiring students to construct their own responses. The items were organised in groups based on a passage setting out a real-life situation. A total of about 390 minutes of test items were covered, with different students taking different combinations of test items.
- Students answered a background questionnaire, which took 30 minutes to complete, that sought information about themselves, their homes and their school and learning experiences. School principals were given a questionnaire, to complete in 30 minutes, that covered the school system and the learning environment. In some countries and economies, optional questionnaires were distributed to parents, who were asked to provide information on their perceptions of and involvement in their child's school, their support for learning in the home, and their child's career expectations, particularly in mathematics. Countries and economies could choose two other optional questionnaires for students: one asked students about their familiarity with and use of information and communication technologies, and the second sought information about their education to date, including any interruptions in their schooling and whether and how they are preparing for a future career.

WHO ARE THE PISA STUDENTS?

Differences between countries in the nature and extent of pre-primary education and care, in the age of entry into formal schooling, in the structure of the school system, and in the prevalence of grade repetition mean that school grade levels are often not good indicators of where students are in their cognitive development. To better compare student performance internationally, PISA targets a specific age of students. PISA students are aged between 15 years 3 months and 16 years 2 months at the time of the assessment, and have completed at least 6 years of formal schooling. They can be enrolled in any type of institution, participate in full-time or part-time education, in academic or vocational programmes, and attend public or private schools or foreign schools within the country or economy. (For an operational definition of this target population, see Annex A2.) Using this age across countries and over time allows PISA to compare consistently the knowledge and skills of individuals born in the same year who are still in school at age 15, despite the diversity of their education histories in and outside of school.

The population of participating students is defined by strict technical standards, as are the students who are excluded from participating (see Annex A2). The overall exclusion rate within a country was required to be below 5% to ensure that, under reasonable assumptions, any distortions in national mean scores would remain within plus or minus 5 score points, i.e. typically within the order of magnitude of 2 standard errors of sampling. Exclusion could take place either through the schools that participated or the students who participated within schools (see Annex A2, Tables A2.1 and A2.2).

There are several reasons why a school or a student could be excluded from PISA. Schools might be excluded because they are situated in remote regions and are inaccessible, because they are very small, or because of organisational or operational factors that precluded participation. Students might be excluded because of intellectual disability or limited proficiency in the language of the assessment.

In 28 out of the 65 countries and economies participating in PISA 2012, the percentage of school-level exclusions amounted to less than 1%; it was less than 5% in all countries. When the exclusion of students who met the internationally established exclusion criteria is also taken into account, the exclusion rates increase slightly. However, the overall exclusion rate remains below 2% in 30 participating countries and economies, below 5% in 57 participating countries and economies, and below 7% in all countries except Luxembourg (8.4%). In 11 out of the 34 OECD countries, the percentage of school-level exclusions amounted to less than 1% and was less than 3% in 30 OECD countries. When student exclusions within schools were also taken into account, there were 11 OECD countries below 2% and 26 OECD countries below 5%.

(For more detailed information about the restrictions on the level of exclusions in PISA 2012, see Annex A2.)

WHAT KINDS OF RESULTS DOES THE TEST PROVIDE?

The PISA assessment provides three main types of outcomes:

- basic indicators that provide a baseline profile of students' knowledge and skills;
- indicators that show how skills relate to important demographic, social, economic and educational variables; and
- indicators on trends that show changes in student performance and in the relationships between student-level and school-level variables and outcomes.

Although indicators can highlight important issues, they do not provide direct answers to policy questions. To respond to this, PISA also developed a policy-oriented analysis plan that uses the indicators as a basis for policy discussion.

WHERE CAN YOU FIND THE RESULTS?

This is the second of six volumes that present the results from PISA 2012. It begins by defining equity in education and discusses how PISA measures equity. Chapter 2 focuses on the relationship between socio-economic status and student performance in mathematics; Chapter 3 examines various aspects of students' background that have an impact on education outcomes, such as family structure and immigrant background; and Chapter 4 explores the close relationship among educational resources, such as opportunities to learn, teacher quality and quantity, and the school's disciplinary climate, and socio-economic status and performance in mathematics. Whenever comparable data are available, trends between 2003 and 2012 are highlighted, and case studies, examining the policy reforms adopted by countries that have improved in PISA, are presented throughout. The concluding chapter discusses the policy implications of the PISA results.

The other five volumes cover the following issues:

Volume I, *What Students Know and Can Do: Student Performance in Mathematics, Reading and Science*, summarises the performance of students in PISA 2012. It describes how performance is defined, measured and reported, and then provides results from the assessment, showing what students are able to do in mathematics. After a summary of mathematics performance, it examines the ways in which this performance varies on subscales representing different aspects of mathematics literacy. Given that any comparison of the outcomes of education systems needs to take into consideration countries' social and economic circumstances, and the resources they devote to education, the volume also presents the results within countries' economic and social contexts. In addition, the volume examines the relationship between the frequency and intensity of students' exposure to subject content in school, what is known as "opportunity to learn", and student performance. The volume concludes with a description of student results in reading and science. Trends in student performance in mathematics between 2003 and 2012, in reading between 2000 and 2012, and in science between 2006 and 2012 are examined when comparable data are available. Throughout the volume, case studies examine in greater detail the policy reforms adopted by countries that have improved in PISA.

Volume III, *Ready to Learn: Students' Engagement, Drive and Self-Beliefs*, explores students' engagement with and at school, their drive and motivation to succeed, and the beliefs they hold about themselves as mathematics learners. The volume identifies the students who are at particular risk of having low levels of engagement in, and holding negative dispositions towards, school in general and mathematics in particular, and how engagement, drive, motivation and self-beliefs are related to mathematics performance. The volume identifies the roles schools can play in shaping the well-being of students and the role parents can play in promoting their children's engagement with and dispositions towards learning. Changes in students' engagement, drive, motivation and self-beliefs between 2003 and 2012, and how those dispositions have changed during the period among particular subgroups of students, notably socio-economically

advantaged and disadvantaged students, boys and girls, and students at different levels of mathematics proficiency, are examined when comparable data are available. Throughout the volume, case studies examine in greater detail the policy reforms adopted by countries that have improved in PISA.

Volume IV, *What Makes Schools Successful? Resources, Policies and Practices*, examines how student performance is associated with various characteristics of individual schools and of concerned school systems. It discusses how 15-year-old students are selected and grouped into different schools, programmes, and education levels, and how human, financial, educational and time resources are allocated to different schools. The volume also examines how school systems balance autonomy with collaboration, and how the learning environment in school shapes student performance. Trends in these variables between 2003 and 2012 are examined when comparable data are available, and case studies, examining the policy reforms adopted by countries that have improved in PISA, are presented throughout the volume.

Volume V, *Skills for Life: Student Performance in Problem Solving*, presents student performance in the PISA 2012 assessment of problem solving, which measures students' capacity to respond to non-routine situations in order to achieve their potential as constructive and reflective citizens. It provides the rationale for assessing problem-solving skills and describes performance within and across countries and economies. In addition, the volume highlights the relative strengths and weaknesses of each school system and examines how they are related to individual student characteristics, such as gender, immigrant background and socio-economic status. The volume also explores the role of education in fostering problem-solving skills.

Volume VI, *Students and Money: Financial Literacy Skills for the 21st Century*, examines 15-year-old students' performance in financial literacy in the 18 countries and economies that participated in this optional assessment. It also discusses the relationship of financial literacy to students' and their families' background and to students' mathematics and reading skills. The volume also explores students' access to money and their experience with financial matters. In addition, it provides an overview of the current status of financial education in schools and highlights relevant case studies.

The frameworks for assessing mathematics, reading and science in 2012 are described in *PISA 2012 Assessment and Analytical Framework: Mathematics, Reading, Science, Problem Solving and Financial Literacy* (OECD, 2013). They are also summarised in this volume.

Technical annexes at the end of this report describe how questionnaire indices were constructed and discuss sampling issues, quality-assurance procedures, the reliability of coding, and the process followed for developing the assessment instruments. Many of the issues covered in the technical annexes are elaborated in greater detail in the *PISA 2012 Technical Report* (OECD, forthcoming).

All data tables referred to in the analysis are included at the end of the respective volume in Annex B1, and a set of additional data tables is available on line (www.pisa.oecd.org). A Reader's Guide is also provided in each volume to aid in interpreting the tables and figures that accompany the report. Data from regions within the participating countries are included in Annex B2.

1

Defining and Measuring Equity in Education

This chapter discusses how PISA measures equity in education and identifies some of the groups of students across all PISA-participating countries and economies, who are most at risk when education systems do not give all students the same chances to succeed.

By measuring the knowledge and skills of 15-year-olds, PISA offers insights into how participating countries and economies are beginning to develop their future talent pools. Indeed, the new Survey of Adult Skills, a product of the OECD Programme for the International Assessment of Adult Competencies (PIAAC), finds a close correlation between countries' performance in the different cycles of PISA and the proficiency of the corresponding age groups in literacy and numeracy in the OECD Skills Outlook 2013 (OECD, 2013). In analysing results of the PISA assessment in the context of various social characteristics of students and schools, such as socio-economic status, gender and immigrant background, PISA also shows how equitably participating countries and economies are providing education opportunities and realising education outcomes – an indication of the level of equity in the society, as a whole.

What the data tell us

- Of the 39 countries and economies that participated in both PISA 2003 and 2012, Mexico, Turkey and Germany improved both their mathematics performance and their levels of equity in education during the period.
- Australia, Canada, Estonia, Finland, Hong Kong-China, Japan, Korea, Liechtenstein and Macao-China achieve high levels of performance and equity in education outcomes as assessed in PISA 2012.

What people know and what they can do with what they know has a major impact on their life chances (Figure II.1.1). The Survey of Adult Skills shows, for example, that individuals scoring at the highest levels in literacy are almost three times as likely to enjoy higher wages than those scoring at the lowest levels, and those with low literacy skills are also more than twice as likely to be unemployed (OECD, 2013).

How skills are distributed across the population also has significant implications on how economic and social outcomes are distributed within society. The skills survey shows, for example, that higher levels of inequality in literacy and numeracy skills are associated with greater inequality in the distribution of income. If large proportions of adults have low reading and numeracy skills, the introduction and wider diffusion of productivity-improving technologies and work organisation practices can be hampered and that, in turn, will stall improvements in living standards. In other words, today's education is tomorrow's economy.

■ Figure II.1.1 ■

Likelihood of positive social and economic outcomes among highly literate adults

Increased likelihood (odds ratio) of adults scoring at Level 4/5 in literacy on the Survey of Adult Skills (PIAAC) reporting high earnings, high levels of trust and political efficacy, good health, participating in volunteer activities and being employed, compared with adults scoring at or below Level 1 in literacy (adjusted)

Notes: Odds ratios are adjusted for age, gender, educational attainment and immigrant and language background. High wages are defined as workers' hourly earnings that are above the country's median.

Source: Based on data from the Survey of Adult Skills (PIAAC) 2012.

StatLink <http://dx.doi.org/10.1787/888932964794>

And the impact of skills goes far beyond earnings, employment, economic growth and prosperity: in all countries, individuals with lower literacy proficiency are more likely than those with better literacy skills to report poor health, believe that they have little impact on political processes, and are less likely to trust others. Inequity in the distribution of skills across societies is thus reflected in broader social inequities.

PISA defines equity in education¹ as providing all students, regardless of gender, family background or socio-economic status, with similar opportunities to benefit from education. For example, the stronger the impact of a student's socio-economic status on his or her performance, the less equitable the school system. Equity, defined in this way, does not imply that everyone should have the same results, nor does it imply teaching the same material or providing the same resources to all students.

■ Figure II.1.2 ■
Student performance and equity

Source: OECD, PISA 2012 Database, Table II.2.1.

StatLink <http://dx.doi.org/10.1787/888932964794>

PISA consistently finds that high performance and greater equity in education opportunities and outcomes are not mutually exclusive: one does not have to be sacrificed to achieve the other. In 20 of the 23 countries and economies that scored above the OECD average in mathematics in PISA 2012, the strength of the relationship between student performance and socio-economic status (the proportion of the variation in performance described by the variation in socio-economic status) is at or below the OECD average. School systems in Australia, Canada, Estonia, Finland,

Hong Kong-China, Japan, Korea, Liechtenstein and Macao-China achieve high mathematics performance² while the relationship between student performance and socio-economic status is weaker than average. School systems in Austria, Belgium, Denmark, Germany, Ireland, the Netherlands, Poland, Slovenia, Shanghai-China, Singapore, Switzerland and Viet Nam achieve high mathematics performance without introducing greater inequities in education outcomes (Figure II.1.2).

Even more encouraging, trend data from 2003 to 2012 show that, of the 39 countries and economies that participated in both PISA assessments, 13 improved their average mathematics performance. Of these improving countries and economies, Mexico, Turkey and Germany also improved their equity levels, either by reducing the extent to which students' socio-economic background predicts their mathematics performance or by reducing the average difference in performance between advantaged and disadvantaged students. Nine additional countries and economies improved their average performance between PISA 2003 and PISA 2012 while maintaining their equity levels.

Performance differences between socio-economically advantaged and disadvantaged students, immigrant and non-immigrant students, or between those attending rural and urban schools indicate the degree to which an education system is equitable. They often reveal how various student characteristics, or the environment in which students learn, are related to performance. Box II.1.1 provides details on how to interpret performance differences in PISA. Tracking the evolution of these disparities over time can help school systems monitor whether and how inequities in education opportunities and outcomes are growing or shrinking.

Box II.1.1. **What do the PISA scores mean?**

Mathematics was first assessed as the main domain in PISA in 2003. At that time, the mathematics performance scale was standardised to have a mean of 500 score points and a standard deviation of 100 score points. This means that across all OECD countries that participated in PISA 2003, the typical student scored 500 points in mathematics and about two-thirds of students in OECD countries scored between 400 and 600 points. Almost 40% of students scored between 450 and 550 points. A performance gap of 100 points thus represents a large difference in performance. Test results are best understood when compared against a specific standard, such as the average performance of OECD countries or the described proficiency levels on each of the PISA scales. There is neither a top/maximum nor bottom/minimum score in PISA; an individual student, school or school system cannot "pass" or "fail" the PISA test.

An entire proficiency level in mathematics spans about 70 score points – a large difference in the skills and knowledge students at that level possess. Such a gap represents the equivalent of about two years of schooling in the typical OECD country. The average performance difference between two students, each enrolled in one of two consecutive grades (for example, grades 9 and 10) in the typical OECD country, is about 41 score points. As reported in Volume I, the difference in mean performance between the highest- and lowest-performing country in mathematics in PISA 2012 is 245 score points (see Table II.2.1). The average difference in mathematics performance between the top and bottom quarters of students in OECD countries is 128 score points (see Table I.2.3a).

However, most differences in mathematics performance related to socio-demographic characteristics of students or schools are much smaller than an entire proficiency level. In the typical OECD country, boys outscore girls in mathematics by 11 points (see Table I.2.3a), while non-immigrant students score 34 points higher, on average, than their peers with an immigrant background (see Table II.3.4a). Socio-economically advantaged students (in the top quarter of socio-economic status in their country) score an average of 90 points higher than their disadvantaged peers (bottom quarter) (see Table II.2.4a), and students in city schools score about 31 points higher than students in rural schools, on average (see Table II.3.3a).

HOW PISA EXAMINES EQUITY IN EDUCATION OPPORTUNITIES

The quantity and quality of educational resources

Education systems that are successful, both in quality and equity, attract the highest-quality resources to where these resources can make the most difference. PISA provides information on how school systems allocate their resources for education and whether that allocation is related to student or school characteristics, such as socio-economic status, immigrant background or school location.

PISA distributes questionnaires to students and school principals to collect information about the quantity and quality of educational resources available to them. For example, schools are asked about the quality of school infrastructure and the availability of qualified teachers. Students are asked about how much class time is devoted to the subjects they learn and the extent of their after-school learning activities.

PISA measures equity in resource allocation across school systems by analysing the responses to the questionnaires and comparing those responses with performance results. This volume provides a glimpse of some school policies and practices, including resource allocation. Volume IV explores in detail some of the school- and system-based policies and practices, including allocation of educational resources, related to student and school performance and how they reflect the level of equity in a system.

Instructional content and practices

The quantity and quality of educational resources will have no effect on learning if students are not exposed to the course content that they need to master to be able to participate fully in society. For this reason, PISA measures the kinds of mathematics tasks 15-year-olds have encountered in their mathematics classes and their relative familiarity with those tasks, as developed over their school lives. This volume explores how exposure to and familiarity with mathematics concepts and processes, also known as “opportunity to learn” mathematics, varies by student, school and school system, and how that variation affects equity in education outcomes.

PISA also monitors equity in education by exploring the learning environment at school. Data on such issues as teacher-student relations, teacher morale and classroom discipline, all gathered through the questionnaires distributed among students and school authorities, are correlated among themselves and with student performance. Large disparities in the quality of the learning environment within and between schools could indicate inequities in education opportunities.

Combining better performance with greater equity

The countries and economies participating in PISA demonstrate that excellence and equity are attainable under a wide variety of conditions.

National income

High income is neither a prerequisite for nor a guarantee of high performance and equity. As discussed in Volume I, a country's per capita GDP explains about 12% of the between-country variation in average performance among OECD countries, and 21% of the variation among partner countries and economies (see Figure I.2.1).³ Countries and economies of similar wealth show very different mean performance in PISA. For example, Canada and Poland score 518 points on the mathematics assessment, yet per capita GDP in Poland is half that of Canada. Per capita GDP in Japan and France is around the OECD average of USD 35 000, yet mathematics performance in these countries ranges from well above the OECD average in Japan (536 points) to around the OECD average in France. Furthermore, countries with very different per capita GDP show similar performance: Latvia and Luxembourg both perform slightly below the OECD average, but per capita GDP in Latvia is under USD 17 000 USD while it is more than USD 84 000 in Luxembourg (see Table I.2.27).

Countries and economies such as Estonia, Hong Kong-China, Poland, Shanghai-China, Singapore, Slovenia, Chinese Taipei and Viet Nam show that the notion of a world neatly divided between highly developed, educated countries and emerging, low-educated countries is no longer valid. Some emerging economies, particularly in East Asia, are rapidly raising the level and quality of their population's education. As discussed in Volume IV, at first glance it may appear that high-income countries and economies (defined here as those with a per capita GDP above USD 20 000) – and those that can and do spend more on education – show better student performance in PISA. Indeed, high-income countries and economies have an average mathematics performance almost 70 score points higher than that of countries whose per capita GDP is below the USD 20 000 threshold. However, while the relationship between higher income and better performance is marked among those countries below the threshold, among high-income countries, there is no significant relationship between higher income and better performance.

A similar pattern is observed for equity in education. Across all participating countries and economies, per capita GDP is only weakly related with equity in education. There appears to be no relationship between per capita GDP and the strength of the relationship between performance and socio-economic status. Among countries whose per capita

GDP is below the USD 20 000 threshold, higher per capita GDP is positively associated with larger differences in performance between socio-economically advantaged and disadvantaged students and school – in other words, less equity in education outcomes. This relationship is no longer apparent, however, among high-income countries.

As explored in Volume IV, there is no overall relationship between spending on education and average performance. PISA results show that once a certain level of spending is reached, more resources no longer predict higher achievement (see Figure IV.1.8). Expenditure of up to about USD 50 000 per student from the age of 6 to 15 is positively related to higher mean performance but also to disparities in performance between students of different socio-economic status. This finding highlights the importance for countries that are boosting public spending on education from relatively low levels to adopt effective policies on equity.

How countries spend their limited resources matters as much as, if not more than, the amount they are spending. As explored in Volume IV, differences in the allocation of educational resources are generally related to better performance (see Table IV.1.20). In particular, greater equity in the distribution of educational resources is associated with higher mathematics performance. As shown in Figure IV.1.11, even after accounting for per capita GDP, 30% of the variation in mathematics performance across OECD countries can be explained by differences in how educational resources are allocated between advantaged and disadvantaged schools.

Socio-economic heterogeneity

Socio-economic diversity in student populations can coexist with high performance and equity. Of the 23 countries with mean performance above the OECD average, Hong Kong-China and Macao-China have above-average equity and greater socio-economic diversity than average (as measured by the range of socio-economic status between the 5th and 95th percentiles, see Figure II.5.1a) and in Finland socio-economic diversity is average. Among those countries/economies with high performance and average levels of equity (as measured by the strength of the relationship between performance and socio-economic status), Shanghai-China and Singapore both show above-average socio-economic diversity, while the Netherlands, Switzerland, Denmark and Germany have average socio-economic diversity.

Similarly, the proportion of low performers relative to top performers, the range of performance between the top and bottom 25% of students, or simply the variation in performance, is either weakly or not at all related to equity in education. Higher-performing countries and economies tend to show greater variation in performance (see Figure I.2.24), but those differences are only weakly related to socio-economic disparities. For example, in Shanghai-China, Singapore and Chinese Taipei, average performance is high and so is overall variation in student performance (see Table II.2.8a).

Immigrant students

Canada, Hong Kong-China and Macao-China combine high levels of achievement and above-average equity – and more than 30% of students in these countries and economies are immigrants. In fact, performance differences between immigrant and non-immigrant students are relatively small in Canada and Hong Kong-China. By contrast, Spain and Greece show relatively large differences in performance between immigrant and non-immigrant students despite having smaller, although still significant, populations of immigrant students (see Table II.3.4a).

EXAMINING EQUITY THROUGHOUT THIS REPORT

Chapter 2 of this volume analyses equity in education outcomes, particularly the relationship between performance and socio-economic status, at both the student and school levels. Chapter 3 examines an array of student and school characteristics and their relationship with performance. It focuses on family structure, immigrant background, language spoken at home and school location and explores what, if any, impact these characteristics have on student performance. Chapter 4 describes how exposure and familiarity with formal mathematics, opportunity to learn, and resources are distributed across different groups of students. Chapter 5 concludes with a discussion of policy options and implications countries can draw on from the evidence and analysis presented in this volume.

This is not the only volume of the *PISA 2012 Results* publication that covers the issue of equity in education. Volume I introduces gender as an important equity issue. It addresses the myth that girls are systematically worse at mathematics than boys and discusses the complexity of the issue. It also proposes that since mathematics skills are critical for both boys and girls as they pursue further education or a career, inequities related to gender are not only unfair, but also ultimately damaging to the wider society and economy.

Volume III looks at differences in attitudes, behaviour and approaches to learning across gender, socio-economic status, family characteristics and school location. These, too, are associated with inequities in the acquisition of knowledge and skills.

Volume IV examines how the policies and practices adopted in schools and school systems are related to performance and equity. While some of these policies are introduced in this volume, Volume IV discusses them in greater depth.

Notes

1. This definition builds previous PISA cycles and the educational equity framework published in *Education at a Glance 2011: OECD Indicators* (OECD, 2011). In particular, the conceptual framework for this chapter draws heavily from Levin (2010).
2. The focus in this volume is on mathematics performance. Most of the analyses presented in this volume can be replicated for each of the domains assessed in PISA 2012. For the most part, the results are likely to be similar, regardless of the domain, but there may be substantial differences in some areas.
3. Here the measure of per capita GDP used is in PPP terms, that is, in equivalent units or as typically known in purchasing power parity.

2

Equity in Outcomes

This chapter focuses on the relationship between student performance in mathematics and socio-economic status. It examines cross-country differences in this relationship and discusses trends between 2003 and 2012 in equity in education related to socio-economic status, highlighting those countries and economies that have improved both their performance and the level of equity in their education systems.

Across OECD countries, 14.6% of differences in performance among students are explained by disparities in students' socio-economic status, whether the focus is on mathematics, reading or science¹ (Table II.2.1). In countries and economies where this relationship is strong, students from disadvantaged families are less likely to achieve high levels of performance. Some 39 score points – the equivalent of one year of formal schooling – separate the mathematics performance – and the difference is very similar for reading and science – of those students who are considered socio-economically advantaged and those whose socio-economic status is close to the OECD average (Table II.2.1).²

In OECD countries, parents of socio-economically advantaged students (those in the top quarter of the socio-economic distribution in their country, or one standard deviation above the average on the *PISA index of economic, social and cultural status*) are highly educated (95% have attained a tertiary education) and work in skilled occupations (97%). In contrast, the parents of socio-economically disadvantaged students (those in the bottom quarter of the socio-economic distribution in their country, or one standard deviation below the average on the *PISA index of economic, social and cultural status*), have much lower educational attainment, and very few (6%) work in skilled occupations. Advantaged students also report having many more books at home than their disadvantaged peers (282 compared with 69 on average), as well as works of art, classical literature and books of poetry (Table II.2.2). While disadvantaged students have fewer books, cultural possessions and some educational resources at home, a large majority has access to a desk, a quiet place to study, a dictionary, a computer and an Internet connection at home (Table II.2.2). For a more detailed definition of socio-economic advantage and disadvantage, as measured by PISA, see Box II.2.1 below.

Large differences in performance associated with the background of students and schools – whether socio-economic status, immigrant or language background – signal that learning opportunities are not equitably distributed throughout a school system or that not all students have access to the high-quality instruction and material, financial and human resources that could help them succeed in school and beyond.

What the data tell us

- Some 6% of students across OECD countries – nearly one million students – are “resilient”, meaning that they beat the socio-economic odds against them and exceed expectations, when compared with students in other countries. In Korea, Hong Kong-China, Macao-China, Shanghai-China, Singapore and Viet Nam, 13% of students or more are resilient and perform among the top 25% of students across all participating countries and economies.
- Across OECD countries, a more socio-economically advantaged student scores 39 points higher in mathematics – the equivalent of nearly one year of schooling – than a less-advantaged student.

PISA measures performance only among 15-year-olds who are enrolled in education, and has no way to estimate the performance of 15-year-olds who are not enrolled in any educational programme. In most OECD countries, there are very few 15-year-olds who do not attend school, but the situation is different in some partner countries. In these countries, the impact of social background on learning outcomes of 15-year-olds is likely to be underestimated.

This chapter examines how variation in student performance is related to socio-economic status and how this relationship is shaped by the way performance and socio-economic status vary within countries.³ Equity in education opportunities is analysed in the context of mean performance in mathematics.

PERFORMANCE AND SOCIO-ECONOMIC STATUS ACROSS SCHOOL SYSTEMS

While many socio-economically disadvantaged students succeed at school, and many achieve at high levels on the PISA assessment, socio-economic status is still a strong predictor of performance in many countries, and is associated with large differences in performance in most countries and economies that participate in PISA. Socio-economically advantaged students and schools tend to outscore their disadvantaged peers by larger margins than between any other two groups of students.

Still, socio-economic status is not destiny: many countries and economies that have seen improvements in their mean performance on PISA have also managed to weaken the link between socio-economic status and performance.

Sometimes, this results in a narrowing of the gap in performance between advantaged and disadvantaged students. Figure II.2.1 shows the socio-economic gradient, a depiction of the relationship between socio-economic status and performance. This report focuses on the strength of this relationship – PISA's main measure of equity in education outcomes. If this relationship is weak, then a student's socio-economic status does not predict his or her performance. While a single measure cannot capture the many complexities of equity in education, it can provide a useful benchmark against which to compare school systems.

■ Figure II.2.1 ■

Students' socio-economic status and performance, OECD countries

Note: Each dot represents an OECD student picked at random out of ten OECD students.

Source: OECD, PISA 2012 Database.

StatLink <http://dx.doi.org/10.1787/888932964813>

How to read this figure

Every dot in Figure II.2.1 represents a student, chosen at random, from an OECD country (10% of all students in OECD countries are represented in the figure). The horizontal axis represents the student's socio-economic status (as measured by the *PISA index of economic, social and cultural status*). The student's mathematics score in PISA 2012 is shown on the vertical axis. The dark line that appears among the dots represents the relationship between student performance and socio-economic status, what is known as the **socio-economic gradient**. The line depicts the typical performance of a student given his or her socio-economic status. The **strength of the socio-economic gradient** refers to how well socio-economic status predicts performance. When the dots are very close to the dark line, the student's performance in mathematics is the same as would be predicted given his or her socio-economic status, so the socio-economic gradient is considered strong. If the dots are far away from the line, the student's actual performance is not the same as would be predicted by his or her socio-economic status, so the socio-economic gradient is considered weak. The strength of the socio-economic gradient is measured by the proportion of the variation in performance that is explained by differences in socio-economic status.

The **slope of the socio-economic gradient** refers to the impact of socio-economic status on performance, or the average difference in performance between two students whose socio-economic status differs by one unit on the *PISA index of economic, social and cultural status*. As such, it is a summary measure of the differences in performance observed across socio-economic groups. A flat line, parallel to the horizontal axis, implies that there are only small differences in performance related to socio-economic status; in other words, advantaged and disadvantaged students perform equally well. A steep line, however, signals large performance differences related to socio-economic status.

Chapter 5 of this volume presents the socio-economic gradient for all countries and economies that participated in PISA 2012. Most countries show either steep, strong socio-economic gradients or flat, weak gradients. But, as Figure II.2.2 shows, two other combinations are also possible. Australia is the only country where performance differences related to socio-economic status are relatively large (above the OECD average), but the strength of the relationship between performance and socio-economic status is relatively weak (below the OECD average); thus the country shows a steep, weak socio-economic gradient. In Portugal, Chile, Costa Rica and Peru, the relationship between performance and socio-economic status is strong, but performance differences related to socio-economic status are small; thus these countries show flat, strong socio-economic gradients.

■ Figure II.2.2 ■

Comparing countries' and economies' performance in mathematics and equity in education outcomes

Countries/economies with mean mathematics performance above the OECD average			
Countries/economies where the strength of the relationship between mathematics performance and socio-economic status is below the OECD average			
Countries/economies where performance differences across socio-economic groups are below the OECD average			
Countries/economies with mean mathematics performance not statistically different from the OECD average			
Countries/economies where the strength of the relationship between mathematics performance and socio-economic status is not statistically different from the OECD average			
Countries/economies where performance differences across socio-economic spectrum are not statistically different from the OECD average			
Countries/economies with mean mathematics performance below the OECD average			
Countries/economies where the strength of the relationship between mathematics performance and socio-economic status is above the OECD average			
Countries/economies where performance differences across socio-economic spectrum are above the OECD average			
	Mean performance in mathematics	Strength of the relationship between mathematics performance and socio-economic status	Performance difference across socio-economic groups
	Mean score	Percentage of explained variance in mathematics performance	Score-point difference in mathematics associated with one-unit increase in the PISA index of economic, social and cultural status
OECD average	494	14.6	39
Macao-China	538	2.6	17

Note: Countries and economies are presented in three groups: those whose mean performance is above the OECD average, those whose mean performance is not statistically different from the OECD average, and those whose mean performance is below the OECD average. Within each group, countries and economies are ranked in descending order of the strength of the relationship between performance and socio-economic status.

Source: OECD, PISA 2012 Database, Table II.2.1.

StatLink  <http://dx.doi.org/10.1787/888932964813>

Success in education can be defined as a combination of high levels of achievement and high levels of equity in education outcomes. As Figure II.2.2 shows, of the 23 systems that perform above the OECD average in PISA 2012, the strength of the relationship between performance and socio-economic status is weaker than average in 9 countries and economies: Australia, Canada, Estonia, Finland, Hong Kong-China, Japan, Korea, Liechtenstein and Macao-China.⁴ In 12 of the 23 countries and economies (Austria, Belgium, Denmark, Germany, Ireland, the Netherlands, Poland, Shanghai-China, Singapore, Slovenia, Switzerland and Viet Nam), the strength of this relationship is about average. Only in one high-performing country and one high-performing economy – New Zealand and Chinese Taipei – is the relationship between performance and socio-economic status stronger than average (Figure II.2.2).

As discussed below, since 2003, Turkey, Mexico and Germany saw both an improvement in overall mathematics performance and greater equity in education outcomes. Moreover, among the other countries and economies that show improvement since PISA 2003, all but one either maintained or improved their equity levels, showing how improvements in mathematics performance need not come at the expense of equity in the school system. Box II.2.4 provides more details on Mexico's improvement in PISA, including the education policies and programmes the country implemented over the past decade. Similarly, Box II.3.2 outlines the path to Germany's improvement, and Box I.2.5 (in Volume I of this series) focuses on Turkey's improvement in PISA.⁵

Box II.2.1. **What is socio-economic status and how is it measured?**

Socio-economic status is a broad concept that summarises many different aspects of a student, school or system. A student's socio-economic status is estimated by an index, the *PISA index of social, cultural and economic status*, which is based on such indicators as parental education and occupation, the number and type of home possessions that are considered proxies for wealth, and the educational resources available at home. The index is built to be internationally comparable (see the *PISA 2012 Technical Report* [OECD, forthcoming]). Students are considered socio-economically advantaged if they are among the 25% of students with the highest *PISA index of social, economic and cultural status* in their country or economy; socio-economically disadvantaged students are those among the 25% of students with the lowest *PISA index of social, economic and cultural status*.

PISA consistently finds that socio-economic status is associated with performance at the system, school and student levels. These patterns reflect, in part, the inherent advantages in resources that relatively high socio-economic status provides. However, they also reflect other characteristics that are associated with socio-economic status but that have not been measured by the PISA index. For example, at the system level, high socio-economic status is related to greater wealth and higher spending on education. At the school level, higher socio-economic status is associated with a range of characteristics of a community that might be related to student performance, such as a safe environment, and the availability of quality educational resources, such as public libraries or museums. At the individual level, socio-economic status may be related to parental attitudes towards education, in general, and to their involvement in their child's education, in particular.

In the typical OECD country, a majority of parents (52%) have a tertiary education (ISCED 5 and 6), a small proportion attained secondary education (ISCED 2) as their highest level of education (12%), and the rest (36%) attained other post-secondary qualifications (ISCED 3 and 4). On average, 4% of parents work in elementary occupations (within ISCO major group 9), 16% in semi-skilled blue-collar occupations (within ISCO major groups 6, 7 and 8), 26% in semi-skilled white-collar occupations (within ISCO major groups 4 and 5), and 54% in skilled occupations (within ISCO major groups 1, 2 and 3).⁶ On average, more than 90% of students enjoy a desk, a quiet place to study, a dictionary, an Internet connection and a DVD player at home. Books of poetry are one of the least common household possessions: fewer than 50% of students reported reporting having them at home. Classical literature and educational software are also relatively uncommon, followed by technical reference books and works of art. The average household has over 155 books (Table II.2.3). This general profile differs widely across countries. For example, in Iceland, parents have spent an average of more than 16 years in education, while parents in Turkey have spent an average of less than nine years in education. On average, students in Hungary, Korea and Luxembourg reported having more than 220 books at home, while those in Brazil, Colombia and Tunisia reported having fewer than 45 books at home (Table II.2.3).

...

In OECD countries, parents of socio-economically advantaged students are highly educated: the majority (95%) has attained tertiary education and nearly all (97%) work in a skilled occupation. One of the home possessions that most clearly distinguishes advantaged students from their peers is the quantity of books at home. Socio-economically advantaged students reported having 282 books at home, on average – compared to an average of 69 books reported by their disadvantaged peers. Other cultural possessions, such as works of art, classical literature and books of poetry, also characterise advantaged students: at least seven out of ten advantaged students reported having these at home. Advantaged students more than disadvantaged students also reported having technical references books, educational software and a dishwasher at home (Table II.2.2).

In contrast, the parents of socio-economically disadvantaged students have much lower educational attainment. Across OECD countries, most parents of disadvantaged students (almost 55%) attained some post-secondary education, 35% attained secondary education (or less) as their highest level of formal schooling, and only 10% attained tertiary education. Very few disadvantaged students have a parent working in a skilled occupation (6%); most parents of these students work in white-collar semi-skilled occupations (41%). Some 39% work in elementary occupations and 13% work in blue-collar semi-skilled occupations. While disadvantaged students have fewer books, cultural possessions and educational resources at home, at least 84% of them have access to a desk, a quiet place to study, a dictionary, a computer and an Internet connection at home. Most (73%) reported having textbooks at home (Table II.2.2).

Some other material measures of wealth, such as the number of televisions and cell phones in a household, are similar among both advantaged and disadvantaged students; but differences in the number of computers, cars, and rooms with a bath or shower are marked. For example, disadvantaged students have fewer than two computers at home while advantaged students have more than three (Table II.2.2).

The OECD average, however, hides significant variations across countries in each of these elements. For illustrative purposes, this volume looks into some of the components at different points, but caution is advised when analysing differences across individual elements, as they are inevitably only part of a complex story (Table II.2.2).

Disparities in performance related to socio-economic status

On average, the performance difference between advantaged (the top quarter of socio-economic status) and disadvantaged (the bottom quarter of socio-economic status) students is 90 score points, or the equivalent of more than two years of schooling and more than one PISA proficiency level. Disadvantaged students are, on average, more than twice as likely as students who are not considered disadvantaged to score in the bottom quarter of the performance distribution (Table II.2.4a).

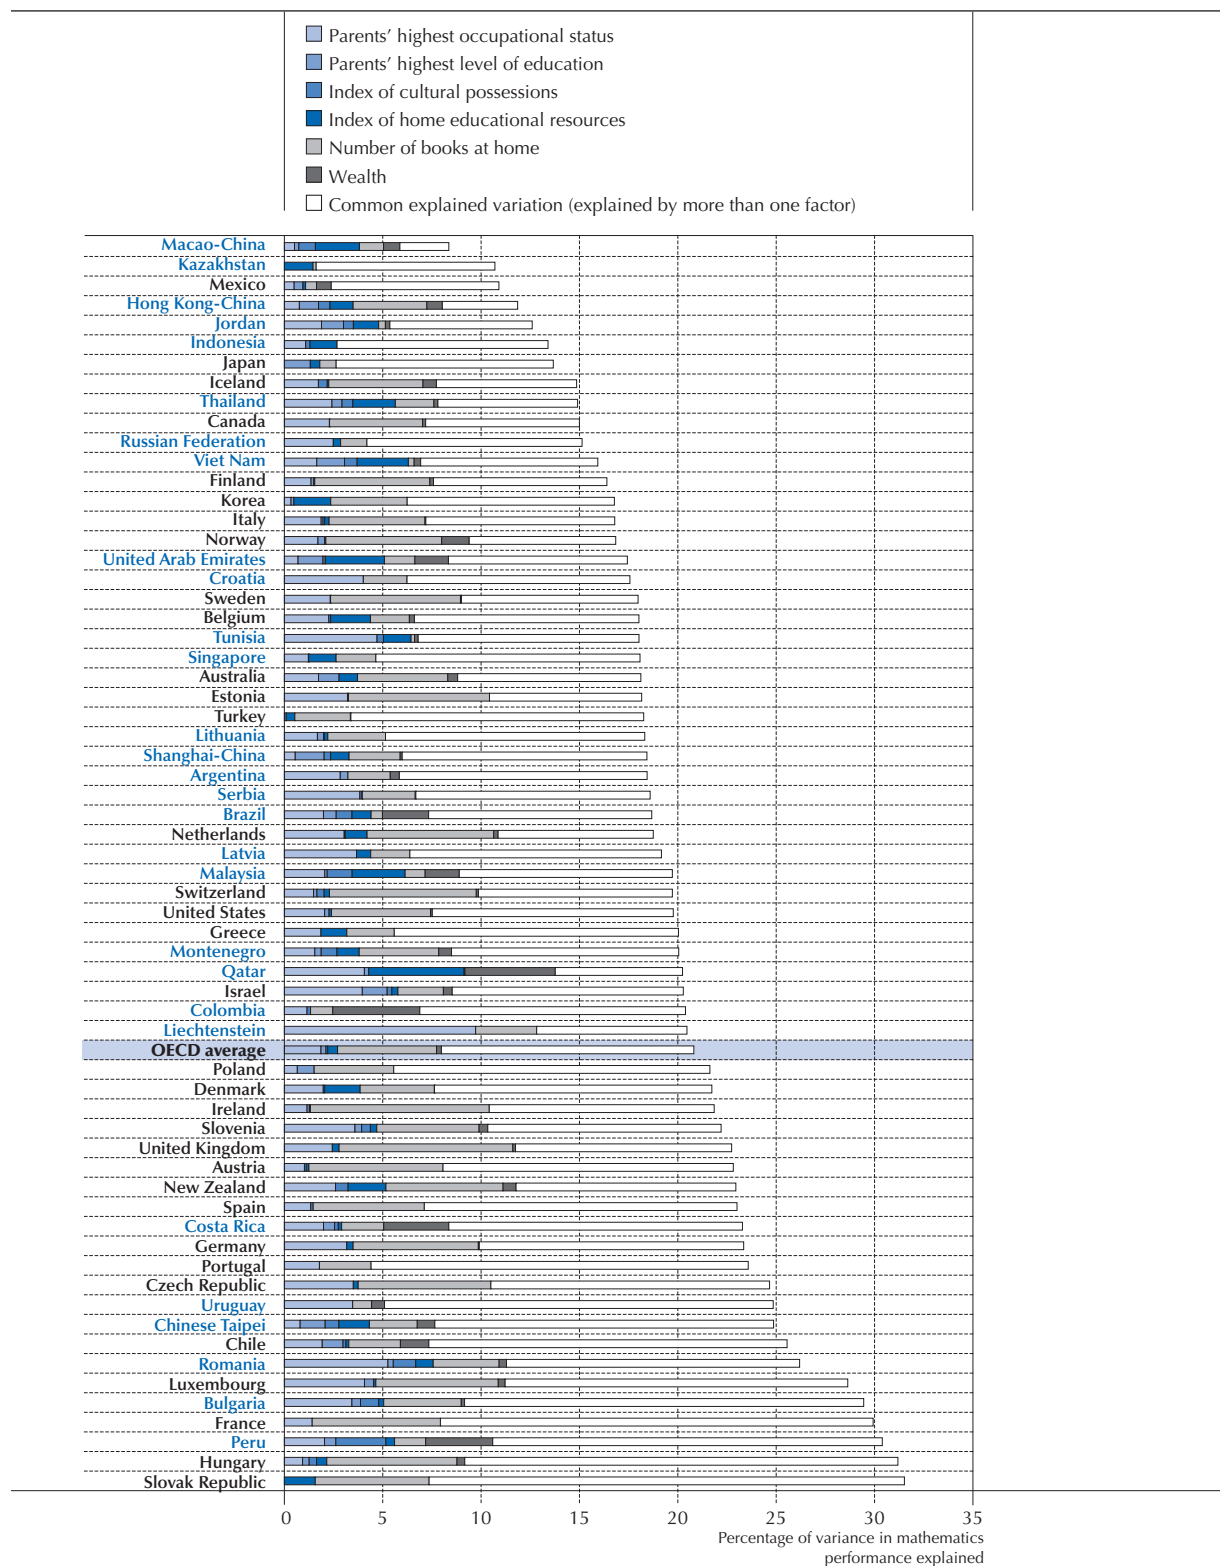

OECD countries with greater equity in education outcomes, as measured by the strength of the relationship between performance and socio-economic status, show smaller performance differences between students from different socio-economic groups, as measured by the slope of the socio-economic gradient. The correlation between the slope and the strength of the socio-economic gradient is 0.61 across OECD countries and 0.57 across all participating countries and economies. Canada, Estonia, Finland, Hong Kong-China and Macao-China combine high performance, a weak relationship between performance and socio-economic status, and relatively narrow performance differences across socio-economic groups. Among high-performing countries, New Zealand and Chinese Taipei are the only two school systems where performance differences are above average and so is the strength of the relationship between socio-economic status and performance. Among countries that perform at or below the OECD average, the same pattern is observed in France, Hungary and the Slovak Republic. Australia is the only country where differences in mathematics performance between advantaged and disadvantaged students are large, but the strength of the relationship between performance and socio-economic status is weaker than average. Chile, Costa Rica, Peru and Portugal are the only countries with relatively narrow performance gaps, despite a strong relationship between socio-economic status and performance (Figure II. 2.2).

The element of socio-economic status that plays a bigger role in explaining these differences varies across countries. For example, across OECD countries, students with highly educated parents outscore students with low-educated parents by 77 score points – equivalent to an entire proficiency level.⁷ A similar gap (84 score points) is observed among students whose parents work in elementary occupations and those whose parents work in skilled occupations.

■ Figure II.2.3 ■

Proportion of the variation in mathematics performance explained by elements of socio-economic status

Countries and economies are ranked in ascending order of the sum of total explained variation in mathematics performance by elements of socio-economic status.

Source: OECD, PISA 2012 Database, Table II.2.6.

StatLink  <http://dx.doi.org/10.1787/888932964813>

In Estonia, the performance gaps associated with parental education and occupation are not as wide, between 53 and 56 score points. However, in Italy and Spain, the performance gaps observed between students whose parents work in different occupations (around 82 score points) are wider than those observed between students whose parents have different levels of education (around 48 and 57 score points, respectively) (Table II.2.5).

Figure II.2.3 summarises, for each country, the degree to which various components of socio-economic status are associated with mathematics performance. Since these components tend to be associated with each other – for example, a student whose parents are better educated is also likely to have parents in higher-status occupations – the graph displays the influence of these features together, and shows the variance in student performance explained by each feature once the influence of the others has been accounted for. The final segment shows the variance explained jointly by all factors (Table II.2.6).

Resilient students

Many socio-economically disadvantaged students, schools and systems still achieve high performance in PISA 2012 by international standards. As Volume IV explains, the amount a country or economy spends on education and its per capita GDP are only weakly related to performance in PISA. Beyond a certain threshold, both of these measures of wealth account for only a limited proportion of the cross-country variation in mean mathematics performance.

Across OECD countries, 6.5% of the entire student population – or nearly one million students – beat the socio-economic odds against them when compared with similar students in other countries. In Hong Kong-China, Korea, Macao-China, Shanghai-China, Singapore and Viet Nam, more than half of disadvantaged students (those in the bottom quarter of the socio-economic scale within a country or economy) or 12.5% of the overall student population perform among the top 25% of students across all participating countries, after taking their socio-economic status into account. Not only do they beat the odds when compared to similar students in other countries, many of these students perform at the highest levels on the PISA scales. PISA refers to these students as “resilient” because they manage to overcome difficult socio-economic circumstances and succeed in school.⁸ Figure II.2.4 shows the percentage of resilient students – as a proportion of the overall student population – across countries and economies and the widely different profiles across school systems (Table II.2.7a).

The share of resilient students increased significantly in Turkey, Mexico, Poland, Italy, Tunisia and Germany, meaning that these countries provided more chances for their disadvantaged students to perform at high levels in 2012 than they did in 2003 (see below for a discussion of trends in equity, and particularly in student resiliency).

Mean performance, after taking account of socio-economic status

Comparing countries’ performance after accounting for socio-economic status allows for comparisons of different education systems based on the performance of students with similar socio-economic status. A simple hypothetical exercise is to analyse the performance of students with an average socio-economic status across OECD countries (that is, at the mean of the index, or zero) and use this as the basis for analysing the performance of the system. The question addressed is: What would be the average performance of this system if all students had the OECD-average socio-economic status?

Most education systems perform similarly before and after accounting for socio-economic status, but there are exceptions.⁹ Figure II.2.5 shows that Portugal would perform above the OECD average if socio-economic status were taken into account. Turkey’s performance would also improve from below average to average. Among the partner economies, Viet Nam would markedly improve its rankings if socio-economic status were taken into account using this simple hypothetical exercise (Table II.2.4). In relative terms, these are the only three countries that would climb more than 10 positions in their performance rankings if socio-economic status were taken into account.

Education systems can also be compared according to the performance of socio-economically advantaged and disadvantaged students (those in the top and bottom quarters of socio-economic status within the country). As Figure II.2.6 shows, in OECD systems that combine high equity in education outcomes and high mean performance, such as Canada, Estonia, Japan and Korea, disadvantaged students rank very highly internationally and so do their advantaged peers.

Among countries and economies with above-OECD-average performance, disadvantaged students in Canada, Denmark, Estonia, Finland, Ireland and Macao-China rank higher than their advantaged peers by more than five positions. Among systems whose mean performance is around the OECD average, the difference is equally marked in Latvia, Norway and Iceland. Among countries and economies with below-OECD-average performance, disadvantaged students in Italy, the Russian Federation and Sweden rank higher than their advantaged peers by more than five positions.

■ Figure II.2.4 ■
Percentage of resilient students

Note: A student is classified as resilient if he or she is in the bottom quarter of the *PISA index of economic, social and cultural status (ESCS)* in the country of assessment and performs in the top quarter of students among all countries, after accounting for socio-economic status. Countries and economies are ranked in descending order of the percentage of resilient students.

StatLink <http://dx.doi.org/10.1787/888932964813>

By contrast, among countries with above-OECD-average performance, advantaged students in Belgium, Germany, New Zealand and Poland rank higher than their disadvantaged peers by more than five positions. The same is observed in the Czech Republic, France and Portugal, among systems that perform around the OECD average, and in Bulgaria, Hungary, Israel, Luxembourg, the Slovak Republic and Uruguay, among those that perform below the OECD average (Figure II.2.6).

Many factors related to socio-economic disadvantage are not directly affected by education policy, at least not in the short term. To what extent can schools and school policies moderate the impact of socio-economic disadvantage on student performance? The overall relationship between socio-economic background and student performance indicates the capacity of education systems to provide equitable learning opportunities. However, from a policy perspective, this relationship is even more important, as it indicates how equity is interrelated with systemic aspects of education. Better schools for disadvantaged students can help reduce socio-economic disparities in performance; but countries also need to consider other policies that affect families, such as those to reduce poverty, malnutrition, and inadequate housing, those to improve parents' education, and other social policies that can also improve student learning.

Between-school variation in performance

Ensuring consistently high standards across schools is a formidable challenge for any school system. Some performance differences between schools may be related to the socio-economic composition of the school's student population or other characteristics of the student body. School location may also explain differences between schools. For example, urban and rural schools often do not provide the same opportunities or have access to the same quantity and quality of resources. In some countries and economies, there is also a large degree of residential segregation based on income or on cultural or ethnic background. In decentralised school systems, performance differences between schools may also be related to differences in the level of government authority responsible for education. Box II.2.2 examines the variation in student performance among the countries that collected regional/state data through PISA.

Box II.2.2. **Geographic location, regions and variation in student performance**

Australia, Belgium, Canada, Italy, Mexico, Spain, the United Kingdom and the partner countries Brazil, Colombia and the United Arab Emirates collected enough data at the sub-national level to allow for a detailed analysis of how student performance varies across different regions and geographical locations. Annex B2 of each Volume of the *PISA 2012 Results* provides in-depth results for those countries that provided results at the sub-national level. Figure II.2.a shows the range of performance across regions compared with mean performance across countries.

For each of the countries listed above, this box describes how much of the variation in students' mathematics performance is observed among students within schools and regions; among schools within regions; and across regions. It also analyses how much of this variation can be described by variations in socio-economic status across students, schools and regions. Table B2.II.25 presents the variation at each level as a proportion of the total variation in performance observed across OECD countries.

Differences in mean mathematics performance across OECD countries account for 10% of the variation in student performance – meaning that performance differences among countries are relatively small compared with performance differences among individual students (see Figure IV.1.2 in Volume IV). In most countries, performance variations across regions account for less than 3% of the variation observed across OECD countries. In Italy, however, performance variations across regions account for almost 8% of the total variation in student performance across OECD countries. In the United Kingdom, there are practically no aggregate performance differences across England, Northern Ireland, Wales and Scotland; however, there are performance differences across schools within regions.

Performance differences among schools within the same region are particularly large in Belgium (they represent 58% of the total variation in student performance across OECD countries) and Italy (45%) compared with the OECD average of 36%. Variations in the performance of students who attend the same school are relatively large in Australia (representing 68% of the total variation in student performance in OECD countries), the United Kingdom (65%), Canada (64%) and Spain (64%), compared with the OECD average of 54% (Table B2.II.25).

...

Figure II.2.a

Mean mathematics performance in countries and regions

Countries and economies are ranked in descending order of mean mathematics performance.

Source: OECD, PISA 2012 Database, Tables I.2.3a and B2.1.3.

StatLink  <http://dx.doi.org/10.1787/888932964813>

Disparities in socio-economic status explain a relative large share of the difference in performance among regions, particularly in some countries, such as Spain and the United Arab Emirates, where differences in socio-economic status among students, schools and regions explain more than 85% of the performance differences observed among regions. The proportion of variation in performance explained in this way is also high in Colombia (70%), Belgium (67%) and Mexico (58%). By contrast, socio-economic differences explain only 16% of performance differences among regions in Canada and 26% in Australia. In Italy, socio-economic status explains 47% of performance differences across regions. In Belgium and the United Kingdom, differences in performance among schools within regions are closely related to socio-economic status. In the United Kingdom, socio-economic status explains 62% of performance differences among schools within the same region, while in Belgium, socio-economic status explains 71% of performance differences among schools located in the same region. By contrast, in Canada, Mexico and the United Arab Emirates, socio-economic status explains less than 50% of the differences among schools located in the same region (across OECD countries, an average of 48% of the performance differences among schools in the same region is so explained). In most countries, socio-economic disparities among students in the same school account for only 3% of the performance differences observed within schools. In Spain, however, 9% of the performances differences observed within schools are so explained (Table B2.II.25).

Between-school differences in performance may also be related to the quality of the school or staff or to the education policies implemented in some schools and not in others. System-level policies may also help to explain why student performance varies between schools. Systems with small between-school variations in performance are those that, in general, are comprehensive, meaning that they do not differentiate by programme, school or student ability. Other systems try to meet the needs of each student by creating different tracks or pathways through education and inviting students to choose among them at an earlier or later age. Volume IV of this publication examines how both school policies and practices and system-level policies vary and relate to performance differences between students and schools.

Figure II.2.7 shows the variation in performance within each country. The length of the bar represents the total variation in that country as a proportion of the OECD average level of variation in performance. The dark part of the bar represents the proportion of those differences that is observed between schools, the light bar represents the proportion of those differences that is observed within schools.

Across OECD countries, 37% of the overall performance differences are observed between schools and 63% within schools. The extent of between-school differences in performance varies widely across school systems.¹⁰ For example, between-school differences account for less than 15% of the OECD average total variation in performance in Estonia, Denmark, Norway, Sweden, Iceland, Finland and Albania. Because Denmark, Estonia and Finland also manage to achieve higher-than-average mean performance, in these countries and economies parents and students can expect that, no matter what school they attend, they are likely to achieve at high levels. In contrast, in Chinese Taipei, the Netherlands, Liechtenstein, Hungary, Belgium and Turkey differences between schools account for more than 60% of the OECD average variation. The overall level of variation in these countries tends to be larger than average, particularly in Chinese Taipei and Belgium (Figure II.2.7 and Table II.2.8a).

Performance differences across schools and socio-economic disparities

More than half of the performance differences observed across students in different schools can be accounted for by socio-economic disparities across students and schools, on average across OECD countries (Figure II. 2.8). A student's study programme, identified through the PISA student questionnaire and other sources, also plays a significant role in explaining performance differences across schools in many countries, accounting for 40% of the differences. The programme is identified by education level (e.g. upper or lower secondary), orientation of the curriculum (e.g. general or vocational), and intent (e.g. providing general access to other education levels or direct access to the labour market). Across OECD countries, 71% of the performance differences across students in different schools is accounted for by a combination of socio-economic status and the student's study programme (Table II.2.9a).

Source: OECD, PISA 2012 Database, Table II.2.9a.

StatLink <http://dx.doi.org/10.1787/888932964813>

Equity between schools is greater in countries with greater equity in outcomes in general, as measured by the strength of the relationship between performance and socio-economic status, including school systems with high average mathematics performance, such as Canada, Finland and Hong Kong-China. In all three, less than 45% of between-school differences in performance is explained by socio-economic disparities. Socio-economic disparities between schools are closely associated with performance differences in Luxembourg, where 93% of the between-school variation in performance is explained by the socio-economic status of students and schools. In Chile, Hungary, Ireland, New Zealand, Peru and Slovenia, more than 75% of the performance differences between schools is explained by the socio-economic status of students and schools.

Students' study programmes are strongly related to performance differences between schools in Germany, Luxembourg and the Netherlands, where more than 80% of the performance variation is explained by the programme in which a student is enrolled. After taking the socio-economic status of students and schools into account, in Belgium, Germany, Luxembourg, the Netherlands, Portugal and Shanghai-China, 85% or more of between-school performance differences is explained by students' study programmes and their socio-economic status, and schools' socio-economic profiles (Table II.2.9a).

Across OECD countries, the socio-economic status of students and schools and students' study programmes are more weakly associated with the differences in performance observed between students who attend the same school (within-school variation).¹¹ In Denmark, Finland, New Zealand, Poland, Portugal, Spain and Sweden, between 9% and 10% of the performance difference within schools can be explained by differences in students' socio-economic status. In Luxembourg, Macao-China, Malaysia, the Netherlands and Portugal, socio-economic status and study programmes explain between 20% and 38% of performance differences within schools (Table II.2.9a).

Box II.2.3. **What are the main characteristics of students attending socio-economically advantaged and disadvantaged schools?**

Advantaged (disadvantaged) schools are those where the typical student in the school, or the socio-economic profile of the school, is above (below) the socio-economic status of the typical student in the country, and the country's/economy's mean socio-economic status. In each school, a random sample of 35 students participate in PISA (for more details, see *PISA 2012 Technical Report* [OECD, forthcoming]). Since the socio-economic profile of the school is calculated using the information provided by these students, the precision of the estimate depends on the number of students in the school who take the test and the diversity of their answers. This was taken into account when classifying schools as advantaged, disadvantaged or average. If the difference between the school's socio-economic profile and the socio-economic status of the typical student in the country (the mean socio-economic status at the country level) was not statistically significant, the school was classified as a socio-economically average school. If the school profile was statistically significantly above the country mean, the school is classified as an advantaged school. If the profile was below the country mean, the school is classified as a disadvantaged school. Schools in which only a few students participated in PISA are therefore more likely to be categorised as socio-economically average schools.

Across OECD countries, 73% of students attending advantaged schools have at least one parent with a tertiary education (ISCED levels 5 and 6) compared with 33% of students in disadvantaged schools. While 77% of students in advantaged schools have parents who work in skilled occupations (ISCO major groups 1, 2 and 3), only 32% of students in disadvantaged schools have parents who work in those occupations. Some 61% of students in advantaged schools have poetry books at home, while 36% of students in disadvantaged schools do. However, there are wide variations in the averages across countries. For example, among OECD countries, in Canada, Finland and Sweden more than 80% of students in advantaged schools and more than 50% of students in disadvantaged schools have tertiary-educated parents. In contrast, in Israel, Japan, Korea and the United States, while more than 80% of students in advantaged schools have highly educated parents, fewer than 40% of students in disadvantaged schools do. There is also wide variation across school systems in the proportions of students in advantaged and disadvantaged schools whose parents work in high-status occupations (Table II.2.10).

Figure II.2.9

Performance differences within and between schools across socio-economic groups

Countries and economies are ranked in ascending order of the between-schools score-point difference associated with a one-unit increase in the student-level PISA index of economic, social and cultural status.

■ Figure II.2.10 ■

Mathematics performance of students in socio-economically advantaged, average and disadvantaged schools

1. A socio-economically disadvantaged school is one whose students' mean socio-economic status is statistically significantly below the mean socio-economic status of the country/economy; an average school is one where there is no difference between the school's and the country's/economy's mean socio-economic status; and an advantaged school is one whose students' mean socio-economic status is statistically significantly above the country/economy mean. Countries and economies are ranked in descending order of the mean performance of students in disadvantaged schools.

StatLink <http://dx.doi.org/10.1787/888932964813>

Figure II.2.11

Distribution of students across school performance and socio-economic profile¹

1. A socio-economically disadvantaged school is one whose students' mean socio-economic status is statistically significantly below the mean socio-economic status of the country/economy; an average school is one where there is no difference between schools' and the country's/economy's mean socio-economic status; and an advantaged school is one whose students' mean socio-economic status is statistically significantly above the country/economy mean. A low-performing school is one in which average school performance is statistically significantly below the mean performance in the country/economy; an average-performing school is one in which there is no difference between the two; and a high-performing school is one in which average school performance is statistically significantly above the country/economy mean. Small schools are more likely to be classified as average schools.

Countries and economies are ranked in ascending order of the proportion of students in low-performing schools that are also disadvantaged schools.

Source: OECD, PISA 2012 Database, Table II.2.11.

StatLink <http://dx.doi.org/10.1787/888932964813>

On average across OECD countries, students attending more socio-economically advantaged schools score 72 points higher in mathematics than students attending a less advantaged school. Within schools, more advantaged students score 20 points higher in mathematics than less advantaged students attending that same school.¹² Figure II.2.9 shows the average performance differences among students attending different schools and among students within the same school, by socio-economic status (Table II.2.9a). Between-school differences in student performance across socio-economic status are relatively small – less than 30 score points – in Finland, Mexico and Spain (41 score points is the equivalent of about one year of formal schooling). However, these differences exceed 140 score points in Japan and the Netherlands.

Students in advantaged schools perform better than those in disadvantaged schools, but they may not perform particularly well when compared against an international standard. Box II.2.3 explains how PISA classifies schools as socio-economically advantaged, average and disadvantaged and describes the main characteristics of these schools. Figure II.2.10 shows the performance of students in advantaged and disadvantaged schools across countries. Across OECD countries, 104 score points separate students in advantaged and disadvantaged schools. While in Finland and Macao-China the differences are relatively small (less than 40 score points; although still large, the difference is smaller than the OECD average), in the Czech Republic, the Netherlands, the Slovak Republic and Chinese Taipei, the gap exceeds 150 score points.

Figure II.2.10 also shows the average socio-economic status of students attending advantaged, average and disadvantaged schools. Some students who attend schools with a relatively disadvantaged student population manage to achieve high levels of performance. For example, students attending disadvantaged schools in Hong Kong-China, Macao-China, Shanghai-China and Singapore score higher than 500 points, on average, in mathematics. Yet the average socio-economic status of these students is well below average, particularly in Hong Kong-China, Macao-China and Shanghai-China, where it is more than one unit below the OECD average (Table II.4.2).

In general, poor performance and socio-economic disadvantage are closely associated at the school level, but some school systems are better than others at weakening that relationship. Across OECD countries, 18% of students attend disadvantaged, low-performing schools and 20% attend advantaged, high-performing schools.¹³ As Figure II.2.11 shows, however, these averages vary widely across countries. In Finland, for example, 4% of students attend disadvantaged, low-performing schools and 6% attend advantaged, high-performing schools. In Norway, Estonia, Canada and Sweden, fewer than 10% of students attend disadvantaged, low-performing schools and fewer than 15% attend advantaged, high-performing schools (Table II.2.11).

PROVIDING ACCESS TO SCHOOLING TO ALL 15-YEAR-OLDS

Access to schooling is a precondition to inclusion and equity in education. Across most OECD countries, all students have access to school throughout compulsory education. Regardless of performance or even equity, any system where a large proportion of 15-year-olds is not enrolled in school cannot be considered a high-quality and equitable education system. Almost all OECD countries achieved universal access to schooling more than a decade ago and enrolment rates in primary and lower secondary education are very close to 100%. Some of the countries that joined the OECD recently and some partner countries have achieved this goal more recently or are moving towards its fulfilment.

Between PISA 2003 and PISA 2012, Indonesia and Brazil added more than 485 000 and 425 000 students, respectively, to the total population of 15-year-olds enrolled in grade 7 or above, an increase of 16% and 18%, respectively, during the period. Adding these new students has been a formidable achievement since in both countries increased enrolment has not led to a decline in learning outcomes. Among OECD countries, Turkey and Mexico also saw an increase in the absolute numbers of students added and in the percentage of enrolled students over the same period. All these countries provided access to schooling to more students – even as the population of 15-year-olds was shrinking, which means that rising enrolment has implied improved capacity to retain students as they progress through higher grades. In the case of Brazil, these achievements are the result of policy measures to minimise grade repetition and dropout (Table II.2.12).

In most countries and economies that participate in PISA, the proportion of 15-year-olds who are not enrolled in school is very small; thus including proxy results for them would have limited impact on an education system's mean performance. For example, one could assume that students outside the education system would score at the lowest level of performance identified in PISA (the lower end of Level 1 in the mathematics performance scale, or 358 score points) and weight these students by their proportion in the population of 15-year-olds. As Table II.2.12 shows, most countries would show no or very small changes in average performance after taking into account the performance of

those outside the school system. Of the six countries and economies where the changes in performance are largest (more than 15 score points; Hong Kong-China, Macao-China, Mexico, Shanghai-China, Turkey and Viet Nam), only Viet Nam would drop a significant number of places in its relative rank (up to 24 places in the ranking, followed by Macao-China, with a loss of up to 10 places).

Box II.2.4. **Improving in PISA: Mexico**

Enrolment in Mexico increased ten-fold between 1950 and 2007, from about 3 million to more than 30 million students. In 2003, 58% of 15-year-olds were enrolled in grade 7 or above. Still, despite continuing increases in enrolment, in 2012, fewer than 70% of the country's 15-year-olds were enrolled in school. In addition to low participation rates, Mexico also faces substantial challenges in providing quality education to its students. In 2012, more than half of Mexican students performed below the baseline level of proficiency in mathematics and fewer than 1% of students were considered top performers in PISA. Average performance still lags well behind the OECD average, to the point that the average Mexican 15-year-old student performs the equivalent of nearly two years below the OECD average.

Yet Mexico has improved its performance over the past decade. Between 2003 and 2012, student performance in reading and mathematics improved. In 2003, the average 15-year-old scored 385 points on the PISA mathematics assessment; in 2012, he or she scored 413 points – an average increase of 3.1 score points per year, which is the third highest increase among OECD countries, but a rate of progress that would still require a quarter of a century for Mexico to catch up with the OECD average. Improvements in performance are largest among the lowest-achieving students: they improved by more than 40 score points – the equivalent of one year of formal schooling – between 2003 and 2012. At the same time, the proportion of 15-year-olds who scored below Level 2 in mathematics dropped 11 percentage points during the period. Although an improvement of more than 20 score points in mathematics in PISA is observed among the highest-achieving students (those in the 90th percentile of mathematics performance), the percentage of students who perform at proficiency Level 5 or above in mathematics remained unchanged between 2003 and 2012.

Reducing the impact of socio-economic status on performance

Mexico was also able to moderate the impact of social background on learning outcomes between 2003 and 2012. The difference in mathematics performance between advantaged and disadvantaged students decreased from around 60 score points in 2003 to around 40 points in 2012. In conjunction with this, the relationship between socio-economic status and performance weakened: in 2003, 17% of the variation in mathematics performance was explained by socio-economic status; in 2012, 10% of the variation was so explained. This means that 15-year-olds' chances of becoming high- or low-achieving students in 2012 were less related to their socio-economic status than they were in 2003. In fact, Mexico's improvement in both mathematics performance and equity since PISA 2003 is largely the result of improvements among disadvantaged and low-performing schools, such that performance differences in PISA between schools have narrowed over the period.

Mexican students' experiences in school also changed between 2003 and 2012. While 30% of 15-year-old students in 2003 reported that they had repeated a grade at least once in their schooling, only 15% reported so in 2012. Students in 2012 spent around 15 minutes more per week in mathematics lessons but around 35 minutes less per week doing homework, on average, than students in 2003 did. Students in 2012 also reported better disciplinary climates in their classrooms and better student-teacher relations than students in 2003 did. In addition, the proportion of teachers hired on an hour-by-hour basis increased from 33% in 2000 to 38% in 2011 (SEP, 2013). These changes in grade repetition, learning time and learning environment, can be considered improvements only if they have led to improved teaching, learning and better student performance. This would not be the case if, for example, students had been promoted automatically at the end of the school year, more learning time had not reduced students' exposure to other equally relevant subjects, and if teachers hired on an hourly basis had to teach in poorer working conditions.

Offering targeted funding and support and independent assessment

During the past decade, Mexico has developed some programmes to promote enrolment in pre-primary education, support schools in need, and generate incentives for students to stay in school. Other, more recent

...

reforms shed light on the policy direction currently taken by Mexico. These reforms include curricular reform and the introduction of assessment and evaluation mechanisms through an independent entity. As these are relatively recent and complex reforms, further studies are needed to assess the extent to which the changes in evaluation, assessment and curriculum explain Mexico's improvement in PISA.

As part of these reforms, pre-primary education was made compulsory in 2002 (the effect of this policy on student performance later on will only be observed in PISA 2015). Work continues on improving the quality of urban care centres for children of low-income and working parents, establishing a national system of day-care centres, and disseminating a framework syllabus to help pre-primary institutions develop curricula that are adapted to their needs.

Education in Mexico, including initial and in-service teacher training, is managed at the state level, but there are mechanisms through which the Ministry implements policies throughout the country. Several targeted funding schemes and support programmes were implemented to promote a more equitable distribution of support and financing, particularly among disadvantaged schools and states. The *Programa Escuelas de Calidad* (PEC, Quality Schools), which was launched in 2001, allocates grants to finance school-improvement plans. It grants autonomy to schools and encourages shared decision making among directors, teachers, parents, union representatives, former students and community members through School Participation Councils. Nearly half of all schools in Mexico have an affiliated Council. The *Plan Estratégico de Transformación Escolar* (PETE) helps stakeholders to develop an annual work plan for which a five-year grant is awarded. Some 70% of the grant for the first four years and 50% of the funds for the fifth year are allocated for supplies, infrastructure and other material resources. Also, between 2009 and 2012, the *Estrategia para la Mejora del Logro Educativo* (EIMLE, Strategy for the Improvement of Educational Achievement) has reached more than 7 000 of the lowest-achieving schools, training networks of teachers and building capacity within the schools through mentorships. The *Programa Escuelas de Tiempo Completo* (PETC, Full-time Schools) aims to lengthen the school day by four hours. It mainly focuses on marginalised urban populations, or populations with large proportions of indigenous, migrant, or other low-performing students. Three years after it was created in 2007, PETC had reached over 2 000 schools across 30 states. Meanwhile, *ConstruyeT*, a programme that focuses on teacher training and practice, reaches one-third of Mexico's schools and enjoys the support of UNICEF, PNUD, UNESCO and 29 NGOs; and the *Better Schools Programme* has refurbished 19 000 pre-primary to lower-secondary schools most in need of repair. Although these programmes mostly target disadvantaged schools and states, the nature of PISA data cannot establish the extent to which, if at all, these programmes have promoted Mexico's performance in PISA (OECD, 2012a).

Other programmes provide incentives for students to stay in school. *Oportunidades* is a cash-transfer programme targeting health and education for families living below the poverty line. The programme began in 2002 and reached more than five million families in 2012, helping to improve enrolment rates in secondary education, particularly among girls. The *Programa de Becas de Media Superior*, another cash-transfer programme, aims to reduce dropout rates at the upper secondary level. These programmes may have contributed to the reduction of dropout rates, but other factors may have contributed as well, inasmuch as dropout rates were declining even before these programmes were implemented (SEP, 2013).

In 2002, the government announced the creation of the *Instituto Nacional para la Evaluación de la Educación* (INEE) charged with measuring and evaluating the education system's quality and performance. The institute was granted complete autonomy from the Ministry of Education in 2013. In line with the idea of creating an information system that would enable stakeholders to follow schools' performance, in 2006, the federal government introduced the National Assessment of Academic Achievement in Schools (ENLACE) to measure student performance across the country. It was applied in each grade after and including grade 3 for Spanish and mathematics. As ENLACE evolved, however, results from the assessment began to be used for multiple, and sometimes conflicting, purposes, and the stakes, for teachers and schools, associated with performance in ENLACE grew. These pressures, and the increasing incentives to "teach to the test", have prompted calls for modifications to be made to the assessment and/or its use (Santiago et al., 2012; OECD, 2013).

In 2012, the government introduced a profound reform of the curriculum, the Comprehensive Reform of Basic Education (RIEB) that places students at the centre of learning. The reform emphasises concepts such as assessment for learning, expected learning outcomes, collaborative learning, project-based work, student self-assessment

...

and peer assessment, and criterion-referenced marking. It also calls for greater co-ordination across the different primary grades and improves continuity with both pre-primary and lower secondary education. The reform faces the challenge of ensuring the proposed changes eventually enter the classroom and alter what and how students are taught. In conjunction with the curricular reform, the RIEB, also continues initiatives begun in the mid-2000s that have extended the school year from 180 to 200 days and made progress towards ensuring a full-day schedule for all schools. In addition, upper secondary education was made compulsory in 2012 with the goal of attaining universal coverage by 2022. Other ongoing policy efforts include professionalising teaching and establishing a teacher-evaluation system.

TRENDS IN EQUITY BETWEEN PISA 2003 AND PISA 2012

By analysing data across different PISA assessments, it is possible to identify those countries and economies that have moved towards a more equitable school system. In 2003, and on average across OECD countries with comparable data for 2012, the slope of the socio-economic gradient was 39 points, meaning that a disadvantaged students (one with value of -1 on the *PISA index of economic, social and cultural status* [ESCS]) scored 39 points lower in the PISA mathematics assessment than a student with average socio-economic status (one with an ESCS value of 0) (Box II.2.5 describes how ESCS can be compared over time). Advantaged students (those with a value of 1 on the ESCS index) were expected to score, on average, 39 points higher than a student with average socio-economic status, and 78 points higher than a disadvantaged student. That year, 17% of the variation in students' mathematics performance, on average across OECD countries, could be explained by students' socio-economic status (OECD, 2004 and Table II.2.5b).

Box II.2.5. Comparing indices in PISA 2003 and PISA 2012

PISA indices, like the *PISA index of economic, social and cultural status*, are based on information gathered from the student questionnaire. In PISA 2012, each index is scaled so that a value of 0 indicates the OECD average and a value of 1 indicates the average standard deviation across OECD countries (see Annex A1 for details on how each index is constructed). Similarly, in PISA 2003, each index was scaled so that a value of 0 indicated the OECD average and a value of 1 indicated the average standard deviation across OECD countries. To compare the evolution of these indices over time, the PISA 2012 scale was used and all index values for PISA 2003 were rescaled accordingly. As a result, the values of the indices for 2003 presented in this report differ from those produced in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004).

Calculating the percentage of resilient students also needs to be adapted to be comparable across time. A resilient student is identified by comparing certain students to the rest of the students who participated in the PISA assessment in any given year. Because more countries and economies participated in PISA 2012 than did in PISA 2003, in order to compare resilience over time, the pooled sample to calculate resilience in 2012 must be based on the same countries and economies that were used to estimate resilience in PISA 2003. As a result, the estimates for resilience for PISA 2012 that are comparable over time differ from those presented for the overall PISA 2012 sample of countries and economies.

By 2012, the OECD average impact of socio-economic status on performance (the slope of the socio-economic gradient; for those OECD countries that have comparable data from PISA 2003 and PISA 2012) remained at 39 score points in mathematics, but the degree to which students' socio-economic status predicted performance in mathematics (the strength of the socio-economic gradient) decreased from 17% to 14%. In other words, by 2012 it was relatively easier than it was in 2003 for students to confound predictions about their performance based on their socio-economic status.

Turkey and Mexico moved towards greater equity by reducing both the slope and the strength of the socio-economic gradient, all the while improving performance. In both Mexico and Turkey the general improvement in mathematics performance also meant that it was easier for students in 2012 than for students in 2003 to confound expectations about performance, given their socio-economic status, and that the average difference in performance between advantaged and disadvantaged students shrank. While in Germany the performance gap between socio-economically advantaged and disadvantaged students remained unchanged, more students were able to overcome that relationship, as measured by the weakening of the socio-economic gradient. Most importantly, in these three countries, the improvement in equity was combined with an improvement in mathematics performance. Other countries and economies that improved mathematics performance (Brazil, Greece, Hong Kong-China, Italy, Macao-China, Poland and Tunisia) maintained their equity levels; only in Portugal were improvements in performance accompanied by a reduction in equity, mainly in the strength of the socio-economic gradient. These results highlight how, for most countries and economies, improvements in performance need not come at the expense of equity (Figures II.2.12 and II.2.13).

■ Figure II.2.12 ■

Change between 2003 and 2012 in the strength of the socio-economic gradient and annualised mathematics performance

Notes: Changes in both equity and performance between 2003 and 2012 that are statistically significant are indicated in a darker tone.

The annualised change is the average annual change in PISA score points from a country's/economy's earliest participation in PISA to PISA 2012. It is calculated taking into account all of a country's/economy's participation in PISA. For more details on the calculation of the annualised change, see Annex A5. Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).

OECD average 2003 considers only those countries with comparable mathematics scores and values on the *PISA index for economic, social and cultural status* since PISA 2003.

StatLink <http://dx.doi.org/10.1787/888932964813>

Another way to determine whether countries and economies are moving towards more equitable school systems is to see how they have promoted student resiliency. Resilient students are disadvantaged students (those in the bottom quarter of a country's or economy's distribution of socio-economic status) who perform in the top quarter of performance in all countries, after accounting for socio-economic status. Countries and economies in which the proportion of students who are resilient is growing are those that are improving the chances for disadvantaged students to become high achievers.

In PISA 2003, 6.4% of students in OECD countries were resilient; by 2012, this share had decreased slightly to 6.1%. Only in Germany, Italy, Mexico, Poland, Tunisia and Turkey did the share of resilient students increase by more than one percentage point. In 11 countries and economies, the share of resilient students shrank – meaning that in these countries/economies it is less likely that disadvantaged students will perform at a high level (Figure II.2.14) (see Box II.2.5 for a description of how resilience is calculated for comparison across PISA assessments).

Consistent with the improvements in student resiliency since 2003, students in the bottom quarter of socio-economic status in Brazil, Italy, Mexico, Poland, Tunisia and Turkey improved their mathematics performance the most between PISA 2003 and PISA 2012. In these countries, for example, a student who, in 2012, was in the bottom quarter of the *PISA index of economic, social and cultural status* scored more than 25 points higher in the PISA mathematics assessment

than a student who was in the bottom quarter of this index in 2003; in Germany, Hong Kong-China, Korea, Portugal and Switzerland students in the bottom quarter of the *PISA index of economic, social and cultural status* improved their performance by at least 15 score points. In Italy, Poland, Portugal and Tunisia, the improvement among disadvantaged students was part of a general improvement in mathematics performance among all students, while in Brazil, Hong Kong-China, Germany, Korea, Mexico, Switzerland and Turkey, the improvement observed among disadvantaged students is considerably larger than the improvement observed – if any – among advantaged students (Table II.2.3b).

■ Figure II.2.14 ■

Change between 2003 and 2012 in student resiliency to socio-economic status

Notes: Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

Resiliency values for 2012 may differ from those shown in Figure II.2.4 as the pooled reference population for resilient students used in this figure is restricted to those countries and economies with comparable data in PISA 2003 and PISA 2012.

The percentage-point difference in the share of resilient students in PISA 2003 and PISA 2012 (2012 - 2003) is shown above the country/economy name. Only statistically significant differences are shown.

OECD average 2003 compares only OECD countries with comparable mathematics scores since 2003.

Countries and economies are ranked in descending order of the percentage of resilient students in 2012.

StatLink <http://dx.doi.org/10.1787/888932964813>

Trends in the profile and distribution of students in schools

Given that a student's peers can be a great source of inspiration and motivation for learning, and given the stigma associated with disadvantaged and low-performing schools, countries and economies striving to provide more equitable learning opportunities generally also aim to attain higher levels of social inclusion. Education policy can play a decisive role in fostering both (OECD, 2012b).

Social inclusion is the degree to which students with different socio-economic status attend the same school or the degree to which different schools have different socio-economic profiles. Increasing social inclusion in a school system – thus reducing socio-economic segregation – has been suggested as the most effective policy to improve equity in both the short and long term, far more effective than creating magnet schools or offering school choice (Eaton, 2001; Wells and Crain, 1997). In 2003, and on average across OECD countries, 76% of the variation in students' socio-economic status was observed within schools. Social inclusion was greatest, at more than 85%, which signals the greatest socio-economic diversity, within schools in Finland, Iceland, Norway and Sweden. The lowest levels of social inclusion (less than 65%) were observed in Brazil, Hungary, Mexico, Thailand and Turkey. In the former group of countries, the socio-economic composition of each school is relatively close to the socio-economic composition of the country/economy; in the latter group of countries/economies, advantaged students are less likely to attend the same school as disadvantaged students, and vice versa.

The degree of social inclusion did not change between 2003 and 2012, on average across OECD countries with comparable data. It decreased in Hong Kong-China, Latvia and New Zealand, but improved in Italy, Japan, Korea, Switzerland and Turkey, meaning that in the schools in these countries, there was a greater mix of students from different socio-economic backgrounds in 2012 than in 2003. Mathematics performance in Italy and Turkey also improved during the period, indicating that greater academic inclusion can coincide with improvements in socio-economic inclusion (Figure II.2.15). Korea's trend towards greater social inclusion is combined with similar levels of academic inclusion (Figure II.2.15 and Table II.2.1b).¹⁴ This means that schools in Korea may have remained as selective in admitting academically proficient students, but that socio-economic status is less a factor in admission to these schools. In Korea, students were more likely to attend schools with students from different socio-economic backgrounds, and were equally likely to attend the same school as students with different academic abilities.

■ Figure II.2.15 ■

Change between 2003 and 2012 in social inclusion

Notes: Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

The index of social inclusion is the percentage of the total variation of student socio-economic status found within schools.

The percentage-point difference in the index of social inclusion is shown above the country/economy name. Only statistically significant differences are shown.

OECD average 2003 compares only OECD countries with comparable mathematics scores since 2003.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).

Countries and economies are ranked in descending order of the index of social inclusion in PISA 2012.

StatLink  <http://dx.doi.org/10.1787/888932964813>

The above discussion looks only at equity in education as it relates to socio-economic status, yet equity refers more broadly to others sources of disadvantage for students. Chapter 3 of this volume explores other potential sources of disadvantage for students, such as where they live, the type of family they come from, including whether they have an immigrant background, and the degree to which different countries and economies are able to limit how these disadvantages influence students' mathematics performance. Chapter 3 also identifies the countries and economies that have succeeded in reducing the impact of these characteristics on students' performance.

Notes

1. Throughout the rest of this volume, the focus is on mathematics performance. While there may be significant differences across the domains assessed in PISA, those differences are outside of the scope of this volume. Therefore, whenever student performance is mentioned it refers to mathematics performance. The percentage of the variance in student performance that can be explained by differences in socio-economic status across students is 14.6%. This statistic corresponds to the r-squared of a simple regression of performance on socio-economic status.
2. That is, those separated by one unit on the *PISA index of social, economic and cultural status*. The index is standardised to have a mean of zero a standard deviation of one across students in OECD countries.
3. Here, variation in student performance is measured by the statistical variance of the student-performance measures, such as the score on the PISA mathematics scale.
4. Here, the focus is on the strength of the relationship between student performance and socio-economic status as measured by the explained variance or r-squared of a simple correlation of performance on socio-economic status.
5. Other volumes of this report highlight other countries' improvements in PISA and outline their recent policy reforms (e.g. Germany in Chapter 3 of this volume, Brazil, Turkey, Korea and Estonia in Volume I, Japan and Portugal in Volume III, and Colombia, Israel, Poland and Tunisia in Volume IV).
6. ISCO major group 0 (armed forces) was divided into two categories and either added to skilled (ISCO 01) or semi-skilled blue-collar occupations (ISCO 03). Students, housewives and vague occupations were coded as missing.
7. Here, highly educated means one or both parents attained tertiary education (ISCED level 5 and 6); low educated means one or both parents attained secondary education (ISCED level 2) as their highest level of education.
8. This measure of resiliency in PISA is a useful one for comparisons among countries. However, it cannot take account of more refined information. For example, a student may have a good or poor testing day or a good or poor learning year or may be shown to be resilient in some subjects and not in others. Furthermore, socio-economic status is a general measure and may not reflect unmeasured differences among and within countries and cultures that would result in a different mode of identification of resilience. Because the identification of resilient students rely on the extremes of the distribution, the measure is less precise.
9. This comparison is based on an international measure of socio-economic status, but disregards the fact that the families of these students may hold very different positions in their own societies. For example, in country where the mean socio-economic status is well below the OECD average, a student with the socio-economic status of the average OECD student may be advantaged when compared with his or her peers. In some countries, the OECD average socio-economic status represents an advantaged status, while in others it does not. Despite these assumptions and the limitations they impose on this exercise, the exercise yields some useful insights.
10. Note that these results also depend on how schools are defined and organised within countries and by the units that were chosen for sampling purposes. For example, in some countries, some of the schools in the PISA sample were defined as administrative units (even if they spanned several geographically separate institutions, as in Italy; in others they were defined as those parts of larger educational institutions that serve 15-year-olds; in still others they were defined as physical school buildings; and in others they were defined from a management perspective (e.g. entities having a principal). The *PISA 2012 Technical Report* (OECD, forthcoming) provides an overview of how schools were defined. Note also that, because of the manner in which students were sampled, the within-school variation includes variation between classes as well as between students. In F638, the primary sampling unit is defined as a group of students who follow the same study programme within a school (an educational track within a school). So in this particular case the between-school variance is actually the within-school, between-track difference.
11. Given the design of PISA, with samples of 35 students per school, and the difficulties in measuring socio-economic status for each student with high precision, this is to be expected. See Hauser (2009) for further details. Hauser (2009), "On 'Quality and Equity in the Performance of Students and Schools'", mimeo available at: https://edsurveys.rti.org/PISA/documents/HauserQuality-Equity_in_PISA_rmh_053009a.pdf
12. The performance gap is larger across schools because it is associated with many school characteristics, such as policies and practices, school location and others that cannot be measured in PISA, that are not included in this analysis. In addition, the analysis of differences within schools draws on less information and on data that are necessarily less precise because it relies only on the information provided by one individual – the student – whereas the school data aggregate information from all the students taking part in the assessment in that school.
13. The definition of high-, average- and low-performing schools is similar to that used for identifying socio-economically disadvantaged, average and advantaged schools. Average school performance is compared with average performance at the system level and schools are classified as high-/low-performing if their average performance is statistically significantly above/below the system's average performance. Both the variance in student performance and the number of observations in a school contribute to the standard error of the estimated average performance at the school level, and therefore to the classification of schools as high-, average- or low-performing.

14. Academic inclusion is the degree to which students with different academic abilities and needs share the same school, or the degree to which schools have different average performance levels. It is also a measure of the likelihood that a country or economy's low- and high-achieving students attend the same school. PISA measures academic inclusion as the percentage of the variation in mathematics performance that occurs within schools; it can also be interpreted as the degree to which students in a school resemble the academic distribution in the country/economy as a whole. The *index of academic inclusion* ranges from 0 to 100 with values closer to 100 indicating greater inclusion.

The Challenge of Diversity

This chapter examines various aspects of students' and schools' characteristics that have an impact on education outcomes, including family structure, parents' job status, school location, immigrant background and language spoken at home. It also discusses trends in immigrant students' mathematics performance up to 2012.

Socio-economic status is only one aspect of a student's background that is related to mathematics performance. Other factors include family structure, school location, immigrant background and language spoken at home (as compared with the language of assessment in PISA). All of these factors have an impact on the work of schools and teachers, and the way in which schools and teachers address them has an impact on education outcomes. They are also in many cases closely related to the socio-economic status of students and schools. This chapter discusses the relationship between student performance and these factors.

Across OECD countries, 13% of 15-year-old students come from single-parent families (Table II.3.1); more than 10% from families affected by unemployment (Table II.3.2); 11% have an immigrant background (Table II.3.4a); 6% are immigrant students who usually speak a language at home that is different from the one in which they are taught at school (Table II.3.5a); and 9% attend schools in small rural communities (Table II.3.3a). This chapter explores equity in education across groups of students who share some of these individual and school characteristics. Analysing equity across different groups of students can help policy makers target or adjust education and social policy to the needs of an increasingly diverse student population.

What the data tell us

- The share of immigrant students in OECD countries increased from 9% in 2003 to 11% in 2012 while the performance disadvantage of immigrant students as compared to students without an immigrant background but with similar socio-economic status shrank by 11 score points during the same period.
- Across OECD countries, students who attend schools where more than one in four students are immigrants tend to perform worse than those in schools with no immigrant students; but after accounting for the socio-economic background of students and schools, the 19-point difference in mathematics scores is more than halved, to 7 score points.

FAMILY STRUCTURE AND STUDENT PERFORMANCE

The family is usually the first place where students can be encouraged to learn. Parents may read to their young children, assist them with homework, and/or participate in school activities (OECD, 2012a). For every student, supportive parents can offer encouragement and meet with teachers or school administrators to keep track of their child's progress in school.¹

Among OECD countries, 13% of the 15-year-old students who participated in PISA 2012 were from single-parent families. Many of them also come from socio-economically disadvantaged backgrounds. On average across OECD countries, students from single-parent families are disadvantaged when compared with students from other types of families generally because their parents have lower educational attainment or work in occupations of lower status, or the family has fewer home possessions as reported by the students themselves (Table II.3.1).

Figure II.3.1 depicts the average mathematics performance of students who live in a single-parent household compared to students in other types of families,² before and after accounting for socio-economic status. Across OECD countries, the performance gap between students from single-parent families and those from other types of families is 15 score points – or the equivalent of almost half a year of schooling – before taking socio-economic status into account.

Students from single-parent families are 1.24 times more likely to score in the bottom quarter of mathematics performance in their country than students from other types of families; this is known as the “relative risk” for students from single-parent households compared with that for students from other types of families (Table II.3.1a). Box II.3.3 presents another way of evaluating the relevance of risk factors, such as family structure or immigrant background, in the entire student population.

In general, accounting for socio-economic status reduces, and in some cases eliminates, the performance gap observed between students from single-parent families and those from other types of families. While family structure is related to socio-economic status, analysis of PISA data cannot disentangle the separate impact of each of these variables on student performance. That performance differences remain marked even after accounting for students' socio-economic status suggests that there is an independent relationship between family structure and education opportunities.

■ Figure II.3.1 ■

Difference in mathematics performance, by type of family*Differences in performance before and after accounting for socio-economic status*

Note: Score-point differences that are statistically significant are marked in a darker tone.

Countries and economies are ranked in ascending order of the score-point difference between students from single-parent families and other types of families, after accounting for socio-economic status.

StatLink  <http://dx.doi.org/10.1787/888932964832>

Box II.3.1. **Population relevance or attributable risk**

One way of measuring the importance of risk factors is through “population relevance”. Population relevance expresses the proportion of the total outcome, such as low mathematics scores, that is associated with membership in a potentially vulnerable population. In the context of single-parent families, the population relevance would measure the extent to which the incidence of poor performance in mathematics among the entire student population would be reduced if the risk of low performance among students from single-parent households were the same as that among students from other types of families. Analysis suggests that if public policy were able to reduce the risk of low performance among students from single-parent families to the same as that among students from other types of families, then the proportion of low-performing students would be reduced by 3% (Table II.3.1). While the relative risk of low performance simply suggests the degree of vulnerability to poor performance a student from particular population is, population relevance provides an absolute measure of how prevalent this source of vulnerability is for the entire student population. The population relevance depends on the relative risk associated with membership in the vulnerable group and on the relative size of the vulnerable group.

On average, after accounting for socio-economic status, students from single-parent families score five points lower in mathematics than students from other types of families. More than 20% of students in Brazil, Chile, Colombia, Costa Rica, Hungary and the United States come from single-parent families and they perform at the same level as their peers from other types of families, after accounting for socio-economic status (before the adjustment, however the performance is lower in the United States, Hungary and Brazil). In Latvia and the Russian Federation, they also constitute more than 20% of the student population and perform better than their peers. As Figure II.3.1 shows, however the gap between these two groups of students is particularly large in Qatar, Jordan, the United Arab Emirates, Belgium and the Netherlands where, after accounting for socio-economic status, the difference is 19 score points or more. In Poland, Chinese Taipei, Tunisia, Malaysia, Greece, the United Kingdom and Japan, the difference is greater than 10 score points (Table II.3.1). In Qatar, Poland, the United States, Jordan, Denmark, Belgium, the United Arab Emirates and Finland the population relevance is higher than 6%; that means that the proportion of low-performing students would decrease by more than 6% if the risk of low performance among students from single-parent households were as low as that of students from other types of families (population relevance) (Table II.3.1).

While the evidence that students from single-parent families perform relatively poorly is discouraging, the variation in performance differences across countries suggests that the relationship is not inevitable. Public policy, in general, and education policies, in particular, can narrow the gaps by making it easier for single parents to support and foster their children’s education (Pong, Dronkers and Hampden-Thompson, 2004). School systems and individual schools can consider, for example, how and what kinds of parental engagement are to be encouraged among single parents who have limited time to devote to school activities. Education policies need to be examined in conjunction with other policies, such as those related to welfare and childcare.

PARENTS’ JOB STATUS: TARGETING EDUCATION POLICIES THROUGH SOCIAL POLICY FOR THE UNEMPLOYED

Education and other social policies play an important role in improving student learning at school. Differences across countries and economies in the impact of parents’ unemployment on student performance suggest that some countries/economies manage to mitigate the potentially negative effects that unemployment has on education outcomes.

On average, 11% of 15-year-old students across OECD countries reported that their fathers’ current job status is “other than working” (full or part time). They reported that their fathers are either currently unemployed (not working but looking for a job) or they hold another job status (home duties, retired, etc.). Some 28% of 15-year-olds reported similar job status for their mother. Parents’ job status is closely linked to socio-economic status, with large gaps in performance between students whose parents are working and those whose parents are not. However, even after accounting for socio-economic status, students in OECD countries who reported that their fathers are not working score six points lower than those who reported that their fathers are working. Students who reported that their mothers are not working score eight points lower than those who reported that their mothers are working. The relative risk of low performance among students with one parent who isn’t working, regardless of which parent it is, is more than 1.4 times greater than for other students. The population relevance is almost 5% when a student’s father is not working and more than 9% when a student’s mother is not working (Table II.3.2).

In the Slovak Republic, Sweden, the Czech Republic, Belgium, Iceland, Hungary and Denmark, parents' job status (of both the father and the mother) is associated with performance gaps ranging from 12 score points in Denmark when students' fathers are not working to 22 score points in Belgium and the Slovak Republic when students' mothers are not working, after accounting for socio-economic status (Figure II.3.2). In Norway, Germany, France, as well as in Croatia, Montenegro, Serbia and Shanghai-China large differences are observed only in relation to mothers' job status. Israel shows the largest performance gap related to mothers' job status (41 score points), but there is no gap related to fathers' job status. Population relevance is highest in the Slovak Republic, Romania, the United Arab Emirates, Hungary, where the proportion of low-performing students would shrink by more than 10% if the risk of low performance among students whose fathers are not working were as low as that of students whose fathers are working; and in Israel, Montenegro, the Slovak Republic, the United Arab Emirates, where the proportion of low-performing students would shrink by more than 20% if the risk of low performance among students whose mothers are not working were as low as that of students whose mothers are working (Table II.3.2).

SCHOOL LOCATION AND VARIATION IN PERFORMANCE ACROSS GEOGRAPHICAL AREAS

In some countries, student performance and the socio-economic or organisational profile of school systems vary considerably according to where schools are located. To capture variation in student performance among school systems and regions within countries, some countries have collected information from PISA at regional levels. Results from these regions are presented in Annex B2 of this volume. Box II.2.2 describes how much of the variation in performance takes place between regions for those countries that collected this information in PISA.

Another way to analyse variation in performance related to geographical characteristics is by school location. Countries vary widely in the densities, characteristics and distributions of populations across different types of communities (Table II.3.3a), and these differences need to be borne in mind when interpreting how students in these different communities perform. Large cities or densely populated areas tend to offer important advantages for schools, such as a richer cultural environment, a more attractive workplace for teachers, more school choice, and better job prospects that can help to motivate students. At the same time, they often pose greater socio-economic challenges. In addition, not all students can enjoy the advantages that large urban centres offer. They may, for example, come from socio-economically disadvantaged backgrounds, speak a different language at home than the one spoken at school, or have only one parent to turn to for support and assistance.

On average across OECD countries, students in schools located in towns (3 000 to about 100 000 inhabitants) outperform students in rural schools (fewer than 3 000 inhabitants) by 11 score points, after taking socio-economic status into account. Students in city schools (more than 100 000 inhabitants) outperform students in town schools by 4 score points, after taking socio-economic status into account (Table II.3.3a).

As Figure II.3.3 shows, after accounting for socio-economic status, students in all schools, regardless of their location, perform above the OECD average in Shanghai-China, Singapore, Hong Kong-China, Chinese Taipei, Viet Nam, Macao-China, Korea, Japan, Liechtenstein, Poland, Switzerland, Estonia, Germany, the Netherlands, Finland, Canada, Austria, and the Czech Republic. In all of these countries except Viet Nam, Japan and Poland, the difference in performance between students in rural schools and those in schools located in large cities is less than 10 score points (Table II.3.3a).

In general, students who attend schools in rural areas tend to score lower than students in schools in other types of locations. The difference is particularly large when performance is compared to that of students in city schools, although differences are observed between students in rural schools and those in schools located in towns. For example, in Slovenia students in city schools outperform those in rural schools by 74 score points, after accounting for differences in students' socio-economic status; but most of that performance gap (65 score points) is already apparent between students in towns and rural areas. Comparing students of similar socio-economic status, the largest performance gaps between students in rural and city schools are observed in Bulgaria, Hungary, Peru, Qatar and Slovenia (above 41 score points or the equivalent of one year of schooling). Students who attend urban schools are, on average, more socio-economically advantaged than those who attend schools in towns. In Belgium, Denmark, Ireland and Turkey, students in town schools perform better than students in city schools, before taking socio-economic status into account; but the differences are not marked. On average in the United States, students in urban schools underperform when compared to those in rural schools, even when they are more socio-economically advantaged (Table II.3.3a).

Figure II.3.3

Mean mathematics performance, by school location, after accounting for socio-economic status

Countries and economies are ranked in descending order of their mean performance of all students, after accounting for socio-economic status.

Source: OECD, PISA 2012 Database, Tables II.2.1 and II.3.3a.

StatLink <http://dx.doi.org/10.1787/888932964832>

Figure II.3.3 also compares the performance of students in large cities across countries, after accounting for socio-economic status. Shanghai-China, Chinese Taipei, Singapore, Hong Kong-China, Viet Nam, Macao-China, Korea, and Japan show the highest mathematics performance – 548 or more score points, on average, among students in city schools, at least one year of schooling above the OECD average.

The difference in socio-economic status between rural and city schools varies considerably across countries. The differences are greatest in Mexico, Bulgaria, Peru, Chile, Colombia, Viet Nam, Thailand, Brazil, Portugal, Hungary, Tunisia and Costa Rica, where the difference is than larger than one unit on the *PISA index of economic, social and cultural status* (Table II.3.3a).

Differences in performance partly reflect differences in the socio-economic status of students who attend schools in urban and rural areas and/or other factors that may be associated with socio-economic disparities that have an impact on student performance. Comparing performance before and after accounting for socio-economic status shows the extent to which differences in student performance related to school location are associated with disparities in socio-economic status among school locations within countries. A large difference in performance both before and after accounting for socio-economic status indicates a significant difference in the socio-economic profiles of urban and rural areas. For example, across OECD countries on average, the performance gap between students who attend schools in rural areas and those who attend schools in towns is 20 score points, but the gap is reduced to 11 score points when students of similar socio-economic status are compared. The difference is greater between rural and city schools, where the estimated difference shrinks from 31 to 13 score points after accounting for socio-economic status (Table II.3.3a).

In PISA 2003 and among the OECD countries that participated in the PISA 2012 assessment, students in rural schools scored an average of 472 points in mathematics, students in schools located in towns scored 497 points, and students in schools located in cities scored 513 points. By 2012, the mathematics performance of students in rural and town schools had not changed, but that of students in city schools had declined by seven points. Across the countries and economies with comparable data for 2003 and 2012 and that show improvements in mathematics performance during this period, the observed improvement is spread across all types of communities. The only exception is Turkey, where much of the improvement observed in mathematics is concentrated among students in town schools who improved their mathematics scores by 59 points between PISA 2003 and PISA 2012, after taking socio-economic differences into account (Table II.3.3b).

EQUITY IN OUTCOMES FOR IMMIGRANT STUDENTS

Migration is not a new phenomenon; but with ageing populations and the looming threat of labour and skill shortages in many OECD countries, the issue has climbed to the top of the policy agenda. Both within and across countries, students with an immigrant background constitute a heterogeneous group. They differ in their country of origin, language and culture, and bring a wide range of skills, knowledge and motivations to their schools. Although a significant subgroup of migrants is highly skilled, that is not true for many others who are socio-economically disadvantaged. Such disadvantage, along with cultural and ethnic differences, can create divisions and inequities between the host society and newcomers. These problems go well beyond how migration flows can be channelled and managed; they require consideration of how immigrants can be integrated into host societies in ways that are acceptable to both the immigrants and the populations in the receiving countries.

Integrating immigrant students into schools is a challenge for most countries; yet a country's success in integrating immigrants' children into society is a key indication of the efficacy of social policy in general and education policy in particular. The variation in performance differences between immigrant and non-immigrant students across countries, even after accounting for socio-economic status, suggests that policy has an important role to play in eliminating those differences. But given the diversity of immigrant student populations across countries, designing education policies to address those students' specific needs – particularly that of language instruction – is not an easy task.

Education policy alone is unlikely to address all the issues related to differences in performance between immigrant and non-immigrant students. For example, immigrant students' performance in PISA is more strongly (and negatively) associated with the concentration of socio-economic disadvantage in schools than with the concentration of immigrants *per se* or the concentration of students who speak a different language at home than the one in which they are taught at school. Reducing the concentration of disadvantage in schools may require changes in other social policy, such as housing or welfare, to encourage a more balanced social mix in schools.

The impact of other social policies on the profile of immigrant students

When interpreting performance gaps between non-immigrant students and those with an immigrant background, it is important to consider the differences in the socio-economic, education and linguistic backgrounds of countries' immigrant populations. The composition of immigrant populations is shaped by immigration policies and practices, and the criteria used to decide who will be admitted into a country vary considerably across countries. While some countries receive relatively large numbers of immigrants each year, often with relatively little selectivity, other countries have much smaller or more selective migrant inflows. In addition, the extent to which the social, educational and occupational status of potential immigrants is taken into account in immigration and naturalisation decisions differs across countries. The composition of past migration flows tends to persist because established networks facilitate migration from the same countries of origin. In addition, some migration flows may not be easily restricted because of international treaties (i.e. free circulation agreements and the Convention relating to the Status of Refugees) or because of generally recognised human rights (i.e. the right of immigrants or citizens to live with their families). As a result, immigrant populations are more skilled or socio-economically advantaged in some countries than in others. Among OECD countries:

- Australia, Canada and New Zealand are countries with immigration policies that favour the better qualified.
- The United States has a migration system that tends to favour family migration, both of the immediate family, as in other countries, and also of parents, siblings and adult children.
- In the 1960s and 1970s, Austria, Denmark, Germany, Luxembourg, Norway, Sweden and Switzerland recruited temporary immigrant workers, many of whom then settled permanently. Immigration increased again over the past ten years, except in Germany. In Austria, Germany and Switzerland, and to a lesser extent in Sweden, immigrants are less likely to have an upper secondary education and more likely to have a tertiary degree. As a result, migrants tend to be of two types – the low-skilled and the highly qualified.
- France and the United Kingdom draw many immigrants from former colonies who have often already mastered the language of the host country.
- Finland, Greece, Ireland, Italy, Portugal and Spain, among other countries, experienced a sharp growth in migration inflows in the early 2000s.

High levels of performance across a diverse student population

PISA distinguishes between three types of student immigrant status: non-immigrant students (those without an immigrant background, sometimes referred to as native students, who were born in the country where they were assessed by PISA or who had at least one parent born in that country);³ second-generation students (who were born in the country of assessment but whose parents are foreign-born); and first-generation students (foreign-born students whose parents are also foreign-born).⁴ This chapter focuses first on immigrant students as a whole (first- and second-generation immigrant students) and then analyses equity in outcomes for first- and second-generation students separately.

Across OECD countries, 11% of the students assessed by PISA 2012 have an immigrant background. These immigrant students tend to be socio-economically disadvantaged in comparison to non-immigrant students. They also score an average of 34 points lower in the PISA mathematics assessment than non-immigrant students, and an average of 21 points lower after accounting for socio-economic differences. In fact, immigrant students are 1.70 times more likely than non-immigrant students to perform in the bottom quarter of the performance distribution. If education policy reduced their vulnerability to poor performance to the levels observed among non-immigrant students, the proportion of low-performing students in the entire population would shrink by 7% (Table II.3.4a).

In Canada, New Zealand and Australia the size of the immigrant student population is well above the OECD average (29, 26 and 23%), and both immigrant and non-immigrant students perform, on average, well above the OECD mean (more than 500 score points). In Australia immigrant students outperform non-immigrants by 29 score points, even after accounting for socio-economic differences. In Canada and New Zealand, both groups perform equally well. The same is true in Ireland, but the proportion of immigrant students (10%) in the country is closer to the OECD average (11%). Among partner countries and economies, Macao-China, Hong Kong-China, Liechtenstein and Singapore also have large proportions of immigrant students and enjoy high levels of average performance among immigrant and non-immigrant students. In Macao-China and Hong Kong-China, immigrant students perform better than non-immigrant students after accounting for socio-economic status; in Singapore the two groups perform equally well; and in Liechtenstein, immigrant students score 40 points lower in mathematics, on average, than non-immigrant students (Table II.3.4a).

StatLink  <http://dx.doi.org/10.1787/888932964832>

Among OECD countries, immigrant and non-immigrant students perform equally well in Canada, New Zealand, Israel, the United Kingdom and Ireland (also in the Slovak Republic, Turkey and Chile, but the size of the immigrant student populations in these countries is less than 1%). In Belgium, France, Switzerland, Austria, Sweden, Spain, Luxembourg, Norway, the Netherlands and Denmark, immigrant students account for 9% or more of the student populations, and they are between 2.0 and 2.3 times more likely than non-immigrant students to score in the bottom quarter of the performance distribution. The same pattern is seen in Colombia, Peru, Finland and Mexico, but in both cases the proportion of students who are immigrants is relatively small – 1% and 3%, respectively. Among partner economies, this pattern is observed in Shanghai-China and Brazil, but the proportion of students who are immigrants is negligible. In Luxembourg, if the risk of low performance among immigrant students were the same as that among non-immigrant students, the proportion of low-performing students in the country would shrink by 31%; in Switzerland, it would shrink by 24%. The proportion of low performers in Belgium, France, Austria, Sweden, Denmark and Germany would also be significantly reduced under that scenario. Only in Liechtenstein, among partner countries and economies, is the population relevance for immigrant students similarly high (Table II.3.4a).

Higher levels of performance among an increasingly diverse student population

In PISA 2003, 9% of students across OECD countries had an immigrant background. They scored 47 points lower in mathematics than their non-immigrant peers; when students with similar socio-economic status were compared, the performance difference was smaller – 33 points – but still present. By 2012, the share of immigrant students across OECD countries with comparable data for 2003 and 2012 increased to 11%, and the difference in mathematics performance in favour of non-immigrant students decreased by around 10 score points. The narrowing of the immigrant student performance gap in mathematics is observed (at 11 score points) even after comparing immigrant and non-immigrant students of similar socio-economic background. Furthermore, the socio-economic status profile of immigrant students in 2012 was slightly more advantaged than that of immigrant students in 2003 (the socio-economic status of non-immigrant students also rose during the period). These results point to the fact that in 2012, and on average across OECD countries, immigrant students face less socio-economic and performance disadvantage when compared to immigrant students in 2003. Despite these changes and the improvements, however, in 2012, immigrant students still faced a significant disadvantage in mathematics performance compared with their non-immigrant peers, albeit to a lesser degree than they did in 2003 (Figure II.3.5).

Among those countries and economies where at least 5% of the student population were immigrants in both 2003 and 2012, in Belgium, Germany, New Zealand, Switzerland and the United States the difference in mathematics performance between students with an immigrant background and those without narrowed between 2003 and 2012 (Figure II.3.5). In Belgium, Germany and Switzerland, the narrowing is the result of greater performance improvements among students with an immigrant background than among students without an immigrant background. In Germany, the performance disadvantage among immigrant students shrank: in 2003, non-immigrant students outscored students with an immigrant background by 81 points in mathematics; by 2012 this difference had decreased to 54 score points (Box II.3.2 outlines Germany's improvement in PISA and their recent policy trajectory). In fact, in Belgium and Switzerland, the reduction is still observed even when comparing students with similar socio-economic status. In the United States, among students with similar socio-economic status, the difference in performance between students with an immigrant and background and those without shrank by 23 points in the period. In Australia, there was no difference in mathematics performance between immigrant and non-immigrant students in 2003; in 2012, immigrant students outperformed non-immigrant students. Only in France and Italy did the performance disadvantage of immigrant students increase between 2003 and 2012. While in Italy this increase is largely explained by the drop in the socio-economic status of immigrant students, in France the increase in the performance disadvantage is observed after comparing students with a similar socio-economic status (Figure II.3.5).

A rapid increase in the proportion of students with an immigrant background – especially in countries and economies that had predominantly non-immigrant populations – poses challenges to education systems. Students with an immigrant background may have different educational needs, particularly if their native language is different from that of the host country; but they also may have different strengths and talents, and school systems need to be aware of both these needs and these strengths if immigrant students are to flourish. Between 2003 and 2012, the share of students with an immigrant background grew by five percentage points or more in Canada, Ireland, Italy, Spain and the United States, and grew by more than ten percentage points in Luxembourg and Liechtenstein. In 2003, the school systems in Ireland, Italy and Spain were predominantly composed of non-immigrant students, but by 2012 the share of immigrant students nearly tripled (Figure II.3.6). In Ireland, the increase in the share of immigrant students is mostly unrelated to changes in their academic disadvantage (Figure II.3.5).

■ Figure II.3.5 ■

Change between 2003 and 2012 in immigrant students' mathematics performance

Notes: Differences in mathematics performance between students without and with an immigrant background in 2003 and 2012 that are statistically significant are marked in a darker tone.

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

The change in the score-point difference in mathematics between students without and with an immigrant background before accounting for students' socio-economic status between 2012 and 2003 is shown above the country/economy name, and the difference after accounting for students' socio-economic status is shown below the country/economy name. Only statistically significant differences are shown.

OECD average 2003 compares only OECD countries with comparable mathematics scores since 2003.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).

Countries and economies are ranked in ascending order of the score-point difference between students with and without an immigrant background before accounting for socio-economic status in 2012.

Box II.3.2. Improving in PISA: Germany

PISA 2000 results placed German students close to the OECD average, highlighting that more than one in five students performed below proficiency Level 2 in reading and that social equity levels in education were among the worst among all OECD countries (OECD, 2010a). Since Germany is a federal country where each *Land* is responsible for its own education system, broad education reform could only occur as the result of a concerted effort among the individual *Länder*. The “PISA shock” that followed publication of the PISA 2000 results was a jolt that spurred reform measures to promote higher quality and greater equity in the school system.

Over the past decade Germany has consistently improved its reading and mathematics performance while improving overall equity in education, as well. Average mathematics scores have improved at an average rate of 1.4 score points per year, from 503 score points in 2003 to 514 points in 2012, with the result that Germany moved from OECD average performance in mathematics in 2003 to significantly above the OECD average in 2012. Performance in reading improved by 1.8 score points per year, from 484 score points in 2000 to 508 points in 2012. Improvements in both subjects are largely the result of better performance among low-achieving and disadvantaged students. In PISA 2012, poor-performing students (the 10% of students with the lowest scores) scored over 20 points higher in mathematics than their counterparts in 2003 did. Similar improvements were observed in reading: in 2012, poor-performing students scored nearly 50 points higher than their counterparts did in 2000.

Because low-achieving students are more likely to come from disadvantaged backgrounds, the observed improvement in mathematics, driven by low-achieving students, also reflects greater equity in the education system.

...

While disadvantaged students (those in the bottom quarter of the *PISA index of economic, social and cultural status*) improved their mathematics performance by 20 score points, no such improvement was observed among students in the second, third or top quarter of the socio-economic scale. As a result, students' socio-economic status is less predictive of their mathematics performance in PISA 2012 than it was in PISA 2003. In 2003, 24% of the variation in mathematics performance was explained by students' socio-economic status; by 2012, 17% of the variation was so explained. During that period, Germany moved from being a country with below-OECD-average equity in education to one with an average degree of equity. Improvements in equity are also evident among students with an immigrant background: in 2003 immigrant students scored an average of 81 points below non-immigrant students in mathematics; by 2012, this disadvantage had narrowed to 53 score points.

Reforms prompted by PISA results

Following the PISA 2000 results, the Standing Conference of Ministers of Education and Cultural Affairs (KMK) defined seven areas of action to improve the quality of the education system. Although these and other education-related recommendations from the KMK that followed were non-binding, most programmes were adopted by most states. To promote the achievement, particularly among disadvantaged children and those with an immigrant background, as well as to promote education opportunities through both in- and out-of-school activities for all students, the national government began to subsidise all-day schools (*Ganztagsschule*). In 2002, one in ten schools was an all-day school; by 2012, more than half of all schools were. Although attendance in all-day programmes is only compulsory in only some schools so far, schools remain open all day, offering lunch and extracurricular activities, supplementary education and instruction in the afternoon for those students who need or want it. One in three students takes part in full-day schools (KMK, 2013).

Another key recommendation from the KMK was to develop binding standards and outcome-oriented evaluations. Following the KMK's recommendation, education standards were introduced in 2003 and 2004 for grades 4, 9 and 10 in German and mathematics. Standards for foreign language instruction (English/French), as well as biology, chemistry and physics were also introduced for grades 9 and 10. Since 2004, each state's curriculum is based on these standards. In addition, assessments were created to measure progress against the standards at both the state and national levels. They are conducted across the 16 federal states, monitoring the performance of individual schools and the school system as a whole. Evaluations at grades 3 and 8 are conducted in every school. Reflecting these changes, students who took part in PISA 2012 were 22 percentage points more likely to attend schools where assessments are used to compare the school against national or regional benchmarks, and 13 percentage points more likely to attend schools where assessments are used to monitor school progress from year to year. Also, students are more likely to attend schools where student assessments are used to evaluate whether students/classes have reached the expected level of achievement and to identify aspects of the curriculum that could be improved. The national results from these assessments are compiled in the *Bildung in Deutschland*, a biennial report on the state of education at all levels.

In 2001, the KMK signalled the need to improve teacher professionalism, particularly regarding skills in diagnosing students and in teaching methods. Changes in these areas are reflected in students' and principals' reports in PISA. Students in 2012 were almost 20 percentage points more likely than students in 2003 were to attend schools where teacher practice is monitored through peer reviews, and 10 percentage points more likely to attend schools where teacher practice is monitored through student achievement. In the past decade, reforms have aimed to strengthen pedagogical training by focusing on new teachers' pedagogical and psychological competencies. In-service teacher training is promoted, with the objective of having all teachers participate in the near future.

In most states, the school system is structured around four years of primary school followed by a three-track school system (*Hauptschule*, *Realschule* and *Gymnasium*) with specific education pathways related to each track. While the *Hauptschule* leads to a vocational and terminal secondary qualification, the *Realschule* is intended for vocational- and academic-track students who want to continue on to vocational/technical or academic tertiary programmes. Many states have begun merging the two vocational tracks into one, motivated by changes in labour market demands that have increased the demand for skills, and demographic changes that have reduced the population of the catchment areas of rural schools.

Concurrent with these reform efforts, social and demographic changes have shifted the profile of Germany's student population. In PISA 2012, socio-economically disadvantaged students and students with an immigrant background had higher levels of the *PISA index of social, economic and cultural status* than disadvantaged

...

students and students with an immigrant background in 2003, and the overall proportion of students that are first- or second-generation immigrants decreased. Also, in 2003, a German student in the bottom quarter of the socio-economic distribution was situated at -1.34 on the ESCS, but a student in the bottom quarter of that index in 2012 was situated at -0.99 (no such change was observed among students in the top quarter of the socio-economic distribution). Similarly, the socio-economic status of students with an immigrant background also improved between PISA 2003 and PISA 2012 (Tables II.2.3b and II.3.4b).

Essentially, these changes mean that the differences in socio-economic status between disadvantaged and advantaged students and between students with an immigrant background and those without have narrowed between PISA 2003 and PISA 2012. These results suggest that Germany's observed improvement in PISA over time may be due to the shifting social and demographic profile of students in parallel to the contribution of any particular policy or programme (Tables I.2.4, I.4.4 and I.5.4).

Box II.3.3. Language minorities among non-immigrant students

Only 4% of 15-year-old students across OECD countries are non-immigrants who do not speak the language of assessment at home. But this proportion varies considerably among countries: in Luxembourg they represent 53% of students; in Belgium and Spain, 14% of students; in Italy, 10%; in the Slovak Republic, 7%; in Turkey, 6%; and in Estonia, Switzerland and Canada, between 3% and 4%. In all countries but Canada, these students are socio-economically disadvantaged when compared with other non-immigrant students. The difference in socio-economic status is widest in the Slovak Republic and Turkey and it is relatively narrow in Switzerland, Estonia and Luxembourg. The difference in mathematics performance between non-immigrant students who do not speak the language of assessment at home and those who do is particularly pronounced in the Slovak Republic where, even after accounting for socio-economic status, 50 score points separate the two groups. In Italy and Switzerland, around 23 score points separate the two groups, and in Estonia, the difference is 14 score points. In Canada and Luxembourg, all non-immigrant students perform at the same level, regardless of the language they speak at home; in Belgium and Spain, they do so after accounting for socio-economic status (Table II.3.8).

In 15 partner countries and economies, non-immigrant students who do not speak the language of assessment at home are a sizable proportion of the student population, and the differences across countries and economies are even greater. These students constitute more than 40% of the student population in Indonesia, Thailand, Malaysia, and Singapore, between 10% and 17% in Chinese Taipei, Qatar and Bulgaria, and between 3% and 10% in Kazakhstan, Lithuania, Latvia, the United Arab Emirates, the Russian Federation, Macao-China, Peru, Jordan and Serbia. In Bulgaria, Peru, Singapore, Thailand, Indonesia, Chinese Taipei, Latvia, the Russian Federation, Serbia, Lithuania and Hong Kong-China these students are socio-economically disadvantaged, compared with other non-immigrant students. In the United Arab Emirates, Qatar, Hong Kong-China, Macao-China, Jordan, Malaysia, and Kazakhstan, they are advantaged compared with other non-immigrant students. Performance gaps in favour of those non-immigrant students who do not speak the language of assessment at home are particularly marked (15 or more score points) in Qatar, Malaysia and the United Arab Emirates. In Singapore, Chinese Taipei, Lithuania, Bulgaria, Peru and Liechtenstein non-immigrant students who speak the language of assessment at home outperform non-immigrant students who do not speak the assessment language at home by more than 10 score points (Table II.3.5).

Language minorities among immigrant students

The most obvious challenge for many students with immigrant parents is adapting to a new language and a new learning environment. The most vulnerable immigrant students are those who arrive at a late age, unable to speak the language of the host country, and from a country where education standards are not as high as those in the host country. Such students would benefit from policies and programmes that take these multiple disadvantages into account. Not all immigrant students face the same challenges; some may be in host countries whose languages and cultures are similar to those in their countries of origin. Ignoring such specific problems may result in the marginalisation of immigrant students at a critical age and with poor prospects for integration (OECD, 2012b).

On average across OECD countries, 6% of 15-year-olds are immigrant students who speak a language at home that is different from the language of assessment. About a third of students in Luxembourg fall into this category as do about 12% of students in Canada, New Zealand, Switzerland and the United States. In Australia, Austria, Belgium, Denmark, France, Germany, Greece, Ireland, Israel, Italy, the Netherlands, Norway, Slovenia, Spain, Sweden and the United Kingdom more than 3% of students are immigrant students who speak a language at home that is different from the language of assessment.

■ Figure II.3.7 ■

Difference in mathematics performance, by immigrant and language background Before and after accounting for socio-economic status

Note: Score-point differences that are statistically significant are marked in a darker tone.

Countries and economies are ranked in descending order of the score-point difference between immigrant students who do not speak the language of assessment at home and non-immigrant students who do.

Source: OECD, PISA 2012 Database, Table II.3.5.

StatLink  <http://dx.doi.org/10.1787/888932964832>

Among partner countries and economies, about 25% of students in Qatar and the United Arab Emirates fall into this category, as do 14% in Singapore, 11% in Liechtenstein, 7% in Macao-China and 4% in Hong Kong-China. In some countries, non-immigrant students who do not speak the language of assessment at home are also a significant proportion of the overall population. Box II.3.3 describes PISA results for this group of students (Table II.3.5).

In Austria, Belgium, France, New Zealand, Sweden and Switzerland the attributable risk or population relevance (a measure of the extent of the population affected by a particular characteristic that puts students at risk of low performance) of immigrant students who do not speak the language of assessment at home was 6% or more; in Luxembourg, it reached 29%. In these countries, the risk of being in bottom quarter of the performance distribution is more than double among immigrant students than among any other students. Among these countries, in Austria, Belgium, Luxembourg, New Zealand and Sweden, the difference in performance between non-immigrant students who speak the language of assessment at home and non-immigrant students who do not is between 30 and 35 score points, after accounting for socio-economic status; in Switzerland, 45 score points separate these two groups; and in Belgium, the difference is 38 score points (Table II.3.5 and Figure II.3.7).

Not understanding the language of the country of residence upon arrival is a disadvantage; but so is insufficient exposure to that language outside of school. Policies aimed at supporting immigrant students who do not speak the language of assessment at home should focus on both school and home. An often-discussed possibility is to provide language lessons to parents and encourage them to become engaged in their child's education, if they aren't already. That can help students to improve their language skills, which, in turn, will improve their performance in school and make integration into the host society easier (for a list of policies implemented in different OECD countries in this area, see the OECD review of migrant education [OECD, 2010b]).

First- and second-generation students

The term “immigrant students” used here includes students whose two parents were born abroad but who, themselves, were born in the country of assessment (second generation) or in another country (first generation). Comparing the performance of first- and second-generation students can provide information about the characteristics of different immigrant cohorts, while comparing these two groups with non-immigrant students can provide an idea of the extent to which school systems manage to integrate immigrant students into schools and the role played by immigration policy.

Some 5% of students across OECD countries, on average, are first-generation immigrant students; 6% are second-generation. In general, there are no significant differences in socio-economic status between the two groups. By contrast, second-generation students score 10 points higher, on average, on the PISA mathematics assessment than first-generation students. Across OECD countries, an average of more than 45 score points separates non-immigrant and first-generation students, while the performance difference between non-immigrant and second-generation students is 30 score points. Accounting for socio-economic status, however, narrows the gaps to 29 and 18 score points, respectively, as immigrant students are generally disadvantaged in comparison to non-immigrant students. On average across OECD countries, if the risk of low performance among first- and second-generation students were as low as that among non-immigrant students, the proportion of low-performing students in the country would decrease by about 4% (Table II.3.6a).

In Australia, Canada, and Ireland, first-generation, second-generation and non-immigrant students perform, on average, at or above the OECD average in mathematics. Except for second-generation students in Ireland, each of these three groups represents at least 8% of the total student population in these countries. In New Zealand, first-generation students perform around or above average, but second-generation students do not. In Hungary, first-generation students perform above the OECD average, but they represent only around 1% of the overall student population. As Figure II.3.8 shows, these differences translate into higher or lower proportions of first- and second-generation students achieving above Level 3 in the mathematics performance compared with non-immigrant students.

The “late-arrival penalty”

In general, the older an immigrant student is when he or she arrives in the host country, the lower his or her score on the PISA mathematics assessment (Table II.3.8). This “late-arrival penalty” appears to be associated with a lack of mastery of the assessment language (OECD, 2012b). More generally, any difficulty in adapting to a different culture and school system, or cross-national differences in education standards, may also contribute to poorer performance among immigrant students.

Figure II.3.8
Percentage of students with mathematics performance below and above the baseline level (Level 2), by immigrant background

Note: This figure shows only countries/economies where data are available for at least one category of immigrant students (first- or second-generation). Countries and economies are ranked in descending order of the percentage of non-immigrant students scoring at Level 3 or above.

Source: OECD, PISA 2012 Database, Table II.3.7.

StatLink  <http://dx.doi.org/10.1787/888932964832>

First-generation students who arrived when they were of lower secondary-school age from less-developed countries where the home language was different from language of assessment in the host country constitute a particularly vulnerable group. These students have to both quickly acquire knowledge of the language of assessment and try to catch up to the performance of their peers in the host country, all while coping with the problems of adjusting to a new school and social environment.

In some cases, students' late arrival is the result of immigration policy. Most countries require that immigrants have adequate lodgings and income before family reunification is allowed. Although such requirements are well-intentioned, the result may be that children have to wait years before they can immigrate, thus making it more difficult for them to integrate into school and into the society of the host country (Heath and Kilpi-Jakonen, 2012). Providing language instruction to older immigrant students is essential.

CONCENTRATION OF DISADVANTAGE

Underperformance among immigrant students can be partly linked to the fact that these students tend to be concentrated in disadvantaged schools (OECD, 2012b). Immigrants tend to settle in neighbourhoods with other immigrants, often of their own origin and socio-economic status, when they move to a new country. By doing so, they build a network of relatives and friends who share their culture and can also help newly arrived immigrants make their way through administrative procedures and perhaps even find work. In addition, early selection or tracking policies in the school system may wind up grouping students of similar origin in the same institution, regardless of where they live. Studies of this phenomenon have shown that the concentration of immigrant students, in itself, need not have adverse effects, provided that there is access to social and public services of a quality comparable to those found elsewhere, and provided that ethnic agglomerations do not become permanent enclaves with little possibility of outward – and upward – mobility (Damm and Rosholm, 2010; Edin, Fredriksson and Aslund, 2004).

This section examines the extent to which the concentration of immigrant or language-minority students is associated with less-favourable education outcomes. The concentration of immigrant students or those who do not speak the language of assessment at home is measured as the proportion of students with such characteristics in each school.⁵

PISA 2012 results suggest that students who attend schools where the proportion of immigrant students is large perform as well as those who attend schools where the proportion of immigrant students is small, after the socio-economic profiles of the students and the school are taken into account. Across OECD countries, students who attend schools where the concentration of immigrants is high (i.e. where more than a quarter of students are immigrants) tend to perform worse than those in schools with no immigrant students. The observed difference between these two groups is 19 score points, but after accounting for the socio-economic status of the students and schools, the difference is more than halved, to eight score points. In fact, Greece and Belgium are the only countries with large immigrant student populations (more than 10%), where there is a large performance difference after accounting for socio-economic status (40 and 35 score points, respectively) (Table II.3.9).

In Estonia, Portugal and Hungary there are also large differences after accounting for socio-economic status, but the size of the immigrant population is smaller. In the Netherlands, Germany and Ireland large performance differences between these two types of schools are observed before accounting for socio-economic status; but most of these differences are strongly related to socio-economic disparities, as they are no longer observed after taking socio-economic status into account. A similar pattern is observed in Slovenia, Italy, Argentina and Finland, but in these countries/economies the immigrant population is smaller (less than 10%). In 14 out of 35 countries with comparable data, students in schools with high concentrations of immigrant students underperform before accounting for socio-economic disparities. After taking socio-economic status into account, the number of countries/economies drops to 7; and in most, the performance gaps are so reduced, or even halved, that they are practically insignificant (Table II.3.9).

A similar pattern is observed when considering the concentration of students who do not speak the language of assessment at home, although differences in performance are larger (Table II.3.10). Across OECD countries, before accounting for students' and schools' socio-economic profile, the difference in mathematics performance between students in schools with high concentrations of students who do not speak the language of assessment at home and those in schools where all students speak the assessment language at home is almost 30 score points, but that difference disappears after taking socio-economic status into account. However, in 16 of the 42 countries with available data, large differences in mathematics performance are observed across these schools; but in all but six of them, those differences are no longer observed after taking socio-economic status into account. Before taking socio-economic status into account, the largest differences are observed in the Netherlands, Bulgaria, Italy, the Slovak Republic, Slovenia, Thailand, Turkey, Mexico and Lithuania. After accounting for socio-economic status, the largest differences in mathematics performances are observed in Hong Kong-China, Switzerland, Indonesia, Greece and Peru.

In general, immigrant students and those who do not speak the language of assessment at home tend to be concentrated in disadvantaged schools (Figure II. 3.9). For example, in the United States, 40% of students in disadvantaged schools are immigrant students, whereas they account for 13% of the student population in advantaged schools. (Table II.4.2). In Hong Kong-China, Macao-China and Luxembourg, the gap in the proportion of immigrant students attending advantaged and disadvantaged is larger than 20 percentage points. A similar pattern is observed among immigrant students who do not speak the language of assessment at home.

■ Figure II.3.9 ■

Proportion of immigrant students in socio-economically disadvantaged, average and advantaged schools¹

How to read this chart: On average across countries and economies, immigrant students represent 11% of the total student population; however, they represent 16% of students attending socio-economically disadvantaged schools, 5% of those attending average schools, and 9% of those attending socio-economically advantaged schools.

1. A socio-economically disadvantaged school is one whose students' mean socio-economic status is statistically significantly below the mean socio-economic status of the country/economy; an average school is one where there is no difference between the schools' and the country's/economy's mean socio-economic status; and an advantaged school is one whose students' mean socio-economic status is statistically significantly above the country's/economy's mean socio-economic status.

Countries and economies are ranked in ascending order of the proportion of immigrant students in socio-economically disadvantaged schools.

StatLink  <http://dx.doi.org/10.1787/888932964832>

PERFORMANCE, IMMIGRANT STATUS AND COUNTRY OF ORIGIN

With increasing inflows of immigrants comes greater diversity in backgrounds – and in education outcomes. Some PISA-participating countries collect information about immigrant students' country of birth and that of their parents, which allows for developing deeper insights into these students' performance and the extent to which host countries are meeting immigrant students' needs. Results from these countries show that immigrant students from the same country and of similar socio-economic status perform very differently across school systems.

Performance differences are large among immigrant students who were born in partner countries. For example, immigrant students from the Russian Federation who are living in Germany outperform those who are living in Greece by more than 75 score points, after taking into account their socio-economic status. Students of Turkish origin living in Belgium outperform Turkish immigrant students of similar socio-economic status, but who are living in Finland by almost 55 score points. On average among host countries with comparable PISA data, immigrant students from Viet Nam score well in mathematics regardless of their country of destination. Those living in Australia attain a mean score of 548 points while those living in the Czech Republic score 524 points.

Among immigrant students from OECD countries, performance differences across host countries are equally large. For example, immigrant students from France who are living in Switzerland outperform French immigrant students living in Israel by more than 60 score points after accounting for socio-economic status. Students of Portuguese origin living in Switzerland outperform those of the same origin and with similar socio-economic status who live in Luxembourg by 58 score points. Immigrant students from Germany living in Austria outperform those living in Belgium by 43 score points (Table II.3.11).

The wide performance differences between students of similar socio-economic status and a common country of origin suggest that schools and education policy in the host countries influence these students' performance. While immigration policies, similarities between the immigrants' and the host culture, and other social policies also explain some of these differences in performance, some education systems appear to facilitate the integration of immigrant students better than others.

Some groups of immigrant students achieve high levels of performance regardless of the country to which they immigrated. For example, immigrant students from China living in Australia and New Zealand are all among the top ten highest-performing groups of immigrant students of all host countries, as are immigrant students from Korea living in New Zealand, and immigrant students from India and Viet Nam living in Australia. Students of German origin in Austria and Luxembourg are the only immigrant students not from Asian countries who are among these top-performing groups.

The mean mathematics performance among all these groups is 548 score points or higher (Table II.3.11), the equivalent of more than one full year of schooling above the OECD average. These students show that it is possible to succeed at school even when confronted with the challenges of adapting to a new country, a new school system and, in many cases, a new culture and language.

Countries that are just beginning to receive increasing numbers of immigrant students from diverse backgrounds can learn from the experience of those systems that have been confronted with this challenge for longer and have succeeded in integrating these students into their school systems. The fact that immigrant students from the same country of origin, cultural backgrounds and socio-economic status perform so differently across host countries indicates that education and social policy can have an impact not only on these students' performance but also on how prepared they are to make the most of available opportunities in their host countries.

Notes

1. The literature on the relationship between family structure and performance is vast, and parental engagement is only one of the aspects analysed in this literature. The literature has focused on the economic situation and, particularly, the stress levels of the family stemming from the transition from one type of family to another and from precarious economic situations. See, for example, Buchmann and Hannum (2001) for a cross-national look at this relationship; McLanahan and Sandefur (1994) for the consequences for students; Raley, Frisco and Wildsmith (2005) for a study of status and stress by comparing single-parent households to cohabitation; and Jeynes (2005) for a discussion about parental involvement in single-parent households. For classic studies on the differences in the use of language by social class, including parent-child interactions and language quality and richness, see Brice Heath (1983). Also, see Volume IV of this report for differences in the types and level of parental involvement in schools across selected PISA countries.
2. Students reported on who usually lives at home with them: a) Mother (including stepmother or foster mother); b) Father (including stepfather or foster father); c) Brother(s) (including stepbrothers); d) Sister(s) (including stepsisters); e) Grandparent(s); Others (e.g. cousin). Students from single-parent families are those who responded “No” and “Yes” to a) and b), or “Yes” and “No” to a) and b). That is, they reported that they live with one parent but not the other. Any other response is categorised as “other”, unless the student did not respond to this question at all.
3. This implies that students who were born abroad but who had at least one parent born in the country of assessment are also classified as students without an immigrant background.
4. If information on only one of the parents is missing, it is assumed that the other parent has the same immigrant background as the one whose information is missing. If the information on the country of birth of the student is missing, the variable is coded as missing.
5. Robustness checks were conducted to exclude schools with few observations, but the results did not change in any significant way.

4

Equity in Opportunities to Learn and in Resources

This chapter explores the concept of equity as it relates to the frequency with which students are exposed to certain mathematics problems in class, teacher quality and quantity, the school's disciplinary climate, and students' participation in pre-primary education. It examines the close relationship among these resources, socio-economic status and performance in mathematics.

Previous research has shown a relationship between students' exposure to subject content in school, what is known as "opportunity to learn", and student performance (Schmidt et al., 2001). Building on previous measures of opportunity to learn (Carroll, 1963; Wiley and Harnischfeger, 1974; Sykes, Schneider and Planck, 2009; Schmidt et al., 2001), the PISA 2012 assessment included questions to students about the mathematics theories, concepts and content to which they might have been exposed in school, and the amount of class time they spent studying these various subjects. As reported in Volume I, there are widely different experiences across systems, schools and students. When these differences are related to student or school characteristics, such as the socio-economic status of students or schools, the proportion of immigrant or minority-language students, or the size of the community in which a school is located, inequities can arise.¹

What the data tell us

- Opportunities to learn formal mathematical problems at school and familiarity with fundamental concepts of algebra and geometry have a stronger impact on performance when the entire student population benefits from them.
- Disparities in exposure to formal mathematics are more marked in school systems that separate students into different schools based on their performance – and, given the strong relationship between performance and socio-economic status, in systems where the unintended result of separation by performance is separation by socio-economic status.
- Across OECD countries, students who reported that they had attended pre-primary school for more than one year score 53 points higher in mathematics – the equivalent of more than one year of schooling – than students who had not attended pre-primary education.
- OECD countries allocate at least an equal, if not a larger, number of teachers to socio-economically disadvantaged schools as to advantaged schools; but disadvantaged schools tend to have great difficulty in attracting qualified teachers.

Volume I of this publication defines and describes a series of indices of exposure and familiarity to formal mathematics based on students' reports. Students were asked about their familiarity with different mathematical concepts. They also reported on how often they had encountered different mathematics problems at school, some focusing on formal mathematics, others on more applied mathematics. These indices provide a measure of the kinds of opportunities to learn mathematics students are exposed to in compulsory education. They reflect what 15-year-old students experience at school but also what they had been exposed to before taking part in PISA. While student self-reports, by definition, give the students' perspective on the types and frequency of mathematics problems to which they are exposed, they may also reflect other student perceptions, such as students' level of comfort with or mastery of these types of problems. Volume I examines how these answers are related to student performance across countries. This section focuses on familiarity with basic concepts of algebra and geometry (such as "quadratic function", linear equation", "polygon" or "cosine") and exposure to formal mathematics problems in school lessons (such as, "Solve: $2x + 3 = 7$ " or "Find the volume of a box with sides 3m, 4m and 5m").

Figure II.4.1 shows the main measures of equity in exposure to formal mathematics and how they relate to mean performance, and the main measures of equity in outcomes. It contains the key data and results discussed in this chapter.

Differences across schools in students' exposure to basic concepts of formal mathematics in algebra and geometry are closely related to performance differences between students attending socio-economically advantaged and disadvantaged schools.² While differences in exposure do not account for all performance differences between these two groups of students, they do account for much of them. Figure II.4.2 shows the relationship among these disparities.

In countries with high mean scores in mathematics and high levels of equity in education outcomes differences between students in advantaged and disadvantaged schools are smaller, both in terms of mathematics performance and exposure to formal mathematics (Figure II.4.1). For example, Estonia, Finland, and Canada, all in the bottom-left quadrant of Figure II.4.2, show narrow performance gaps between students who attend socio-economically advantaged and disadvantaged schools (Figure II.4.2). Among schools systems with high average mathematics achievement and high equity in education outcomes (as measured by the strength of the relationship between performance and socio-economic status) (Figure II.4.1), only Japan and Korea show large differences in student performance and average disparities in opportunities to learn between advantaged and disadvantaged schools (top-right quadrant of Figure II.4.2).

■ Figure II.4.1 ■

Summary of PISA measures of equity in exposure to formal mathematics

		Higher quality or equity than the OECD average	Not statistically different from the OECD average	Lower quality or equity than the OECD average				
	Average student performance in mathematics	Strength of the relationship between student performance and socio-economic status ¹	Performance differences across socio-economic status: Slope of the socio-economic gradient ¹	Mean index of exposure to formal mathematics	Variation of the index of exposure to formal mathematics	Within-school variation of the index of exposure to formal mathematics as a proportion of the sum of the within- and between-school variation	Within-school variation in socio-economic status as a proportion of the sum of the within- and between-school variation	Within-school variation of student performance as a proportion of the sum of the within- and between-school variation

Magnitude of performance differences related to students' exposure to formal mathematics, by schools' socio-economic profile

Between students in advantaged schools and those in disadvantaged schools

Note: Depending on the organisation of schooling (comprehensive vs. institutional differentiation according to performance) differences across schools are to be expected for certain aspects of learning opportunities to meet students' needs.

Source: OECD, PISA 2012 Database, Tables II.4.2 and II.4.3.

StatLink <http://dx.doi.org/10.1787/888932964851>

Figure II.4.2 also shows that, on average across OECD countries, there is a very strong relationship between the differences between advantaged and disadvantaged schools in mathematics performance and in exposure to formal mathematics (the correlation between these two measures is 0.65). On average across OECD countries, the difference in mathematics performance amounts to 104 score points. The difference in exposure to mathematics across school's socio-economic profile is also large (more than 0.45 in the index of exposure of formal mathematics or three quarters of a standard deviation on the index, 0.60). On average, students in advantaged schools reported that they had "often heard of" the more advanced topics of mathematics related to algebra and geometry and had also had "frequent" encounters with problems dealing with formal mathematics, more generally, in class. Students in disadvantaged schools reported that they had heard of these topics somewhere between "once or twice" and "a few times" in class.

DISPARITIES IN EXPOSURE TO FORMAL MATHEMATICS, SOCIO-ECONOMIC STATUS AND PERFORMANCE

Students who are not exposed to mathematics concepts and processes in school cannot be expected to learn (on their own), much less excel at, that material. Allocating more and better resources to education will only go so far; what is taught in the classroom – and how it is taught – ultimately determines whether those resources serve the school system's primary objective: providing high-quality, equitable education to all. Breadth and depth of instructional content and delivery is critical for student learning, particularly in mathematics.

Opportunities to learn may differ across students and schools for many reasons. If the school system tracks students into different schools that distinguish, for example, between academic and vocational pathways, students' exposure to mathematics may vary accordingly, depending on the schools they attend. Exposure to different mathematical concepts and experience with mathematical problems may also differ among students within a particular school, especially when students are grouped by ability and taught different material. Instructional content and delivery may also differ within a school if 15-year-old students are enrolled in different grades within the same school or if students choose different programme strands.

Disparities within countries

On average across OECD countries, 15-year-old students reported that they had heard of mathematical concepts in algebra and geometry “a few times” but had “frequent” encounters with problems involving formal mathematics. While there are significant differences across school systems, there are even larger differences between schools within a country and among students within schools.³ Most of the differences are observed among students who attend the same school (65%); differences between schools within countries account for 17% of the overall differences and differences across countries and economies account for the remaining 18% of the differences.⁴

School systems that combine high average performance and equity tend to offer all their students frequent exposure to formal mathematics concepts (as measured by higher-than-average means on the *index of exposure to formal mathematics* and lower than average overall and between-school variations in the same index). Of the nine countries with high performance and equity, Liechtenstein is the only where mean exposure to formal mathematics is below average. Of this group, only in Australia, Hong Kong-China and Liechtenstein the variation in exposure to formal mathematics is above average. Liechtenstein is the only system where the variation is large and between school differences are above average. Japan and Korea are the only two countries on this group where differences between schools in exposure to formal mathematics are above average (Figure II.4.1).

Differences in exposure to mathematics and average mathematics performance across school systems

Fewer disparities in exposure to mathematics concepts are associated with higher mean performance, particularly in those school systems where the frequency of exposure to and familiarity with formal mathematical concepts is greater than the OECD average. Exposure to formal mathematics problems at school and familiarity with fundamental concepts of algebra and geometry have a stronger impact on average performance when the entire student population has benefited from them. As Figure II.4.3 shows, the countries that achieve high levels of performance tend to show smaller disparities in exposure to formal mathematics.

Figure II.4.3 also shows that when school systems provide frequent exposure to formal mathematics concepts and practices, there is a strong relationship between differences in exposure to formal mathematics and average performance. Estonia, Japan and Korea, for example, all perform well above the OECD average; in addition, exposure to formal mathematics in these countries is also well above the OECD average and differences in opportunities are below average. These patterns are also seen across partner countries and economies, with Shanghai-China achieving particularly high average performance associated with frequent exposure to formal mathematics problems and familiarity with fundamental mathematics concepts in geometry and algebra, and markedly small variations in those opportunities.

When exposure to formal mathematics is below the OECD average, disparities are not strongly related to mean performance (as represented in the left hand side of Figure II.4.3). There are countries that provide less frequent exposure to formal mathematics, have less variation in those opportunities, and show poorer average performance, such as Costa Rica, Luxembourg, and Uruguay; but there are also countries, such as Austria, the Netherlands, New Zealand and Switzerland, that provide less frequent exposure to mathematics, show large disparities in exposure and also show above-average performance (Figure II.4.3).

Between-school differences in opportunity to learn, socio-economic status and performance

In most school systems where there is some kind of selection of students, students tend to be selected into schools on the basis of their performance. As explored in Chapter 2, performance tends to be closely related to socio-economic status; so often the unintended result of separating students by performance is the separation of students by socio-economic status as well. Results from PISA 2012 show that disparities in exposure to formal mathematics are more

marked in systems that separate students into different schools based on their performance – and, given the relationship between performance and socio-economic status, in systems where the unintended result of separation by performance is separation by socio-economic status. Large between-school differences in opportunities to learn, socio-economic status and performance are associated with systems that show lower levels of equity in education outcomes and, in some cases, lower average performance.

■ Figure II.4.3 ■

Relationship between mathematics performance and variation in students' exposure to formal mathematics

Notes: Depending on the organisation of schooling (comprehensive vs. institutional differentiation according to performance), differences across schools are to be expected for certain learning opportunities to meet students' needs.

Countries with mean mathematics performance above the OECD average are marked with an asterisk.

Source: OECD, PISA 2012 Database, Tables I.2.3a and II.4.1.

StatLink <http://dx.doi.org/10.1787/888932964851>

As Figure II.4.1 shows, Canada, Denmark, Estonia, Finland, Iceland and Sweden all show below-average between-school differences in performance, socio-economic status and exposure to formal mathematics. These systems not only succeed in minimising differences between schools across these three indicators, they all show greater-than-average equity in education outcomes, as measured by the strength of the relationship between socio-economic status and performance, except Denmark, where equity is average. Canada, Denmark, Estonia and Finland perform above average, Iceland shows average performance, and only Sweden performs below average.

By contrast, Argentina, Brazil, Chile, Hungary and the Slovak Republic all show large between-school differences in performance, socio-economic status and exposure to formal mathematics. Average performance is below the OECD average in all these school systems. Chile, Hungary and the Slovak Republic also show below-average equity in education outcomes, while equity in Argentina and Brazil is at the OECD average, as measured by the strength of the relationship between socio-economic status and performance.

■ Figure II.4.4 ■

Between-school differences in exposure to formal mathematics, socio-economic status and performance

Note: Depending on the organisation of schooling (comprehensive vs. institutional differentiation according to performance), differences across schools are to be expected for certain learning opportunities to meet students' needs.

Source: OECD, PISA 2012 Database, Tables II.2.8a, II.2.13a and II.4.1.

StatLink <http://dx.doi.org/10.1787/888932964851>

Between-school differences and the overall variation in exposure to formal mathematics are above average in Austria, Belgium, Germany, Liechtenstein, the Netherlands and Switzerland (with above-average performance) and Argentina, Brazil and Italy (with below-average performance). In all of these countries, except Switzerland, between-school differences in performance are below average. Socio-economic differences between schools are above average in Argentina and Brazil, average in Austria, Belgium, Germany and Italy, and below average in Liechtenstein, the Netherlands and Switzerland. None of these countries, except Italy and Liechtenstein, achieves above-average equity in education outcomes, as measured by the strength of the relationship between socio-economic status and performance.

EQUITY IN EDUCATIONAL RESOURCES

A potential source of inequity in learning outcomes and opportunities lies in the distribution of resources across students and schools. A positive relationship between the socio-economic profile of schools and the quantity or quality of resources means that advantaged schools benefit from more or better resources; a negative relationship implies that more or better resources are devoted to disadvantaged schools. No relationship between the two implies that schools attended by disadvantaged students are as likely to have access to better or more resources as schools attended by advantaged students.

■ Figure II.4.5 ■

Summary of PISA measures of equity in educational resources

		Disadvantaged schools are more likely to have more or better resources; correlation is stronger than 0.25						
		Advantaged schools are more likely to have more or better resources; correlation is stronger than 0.25						
	Simple correlation between the school mean socio-economic profile and:							
	Student-teacher ratio ¹	Composition and qualifications of mathematics teaching staff (proportion of teachers with university-level qualifications)	Student-related factors affecting school climate	Proportion of students who leave school without a certificate	Parental pressure to achieve	Attendance at after-school lessons	Hours spent on homework or other study set by teachers

Note: The data are indicated in bold if within-country/economy correlation is significantly different from the OECD average.

1. Negative correlations indicate more favourable characteristics for advantaged students.

Source: OECD, PISA 2012 Database, Table II.4.6.

StatLink  <http://dx.doi.org/10.1787/888932964851>

Figure II.4.5 shows the relationship between the socio-economic profile of schools – the average *PISA index of economic, social and cultural status* of the students in the school – and various school characteristics, such as the student-teacher ratio, the proportion of full-time teachers, the *index of teacher shortage*, and the *index of quality of educational resources* (see Volume IV for more analysis and details about these indices). Relationships involving disadvantaged schools whose principal reported more and/or better-quality resources are coloured light blue; relationships involving disadvantaged schools whose principals reported less and/or lower-quality resources are coloured medium blue. If the relationship in a school system, overall, is stronger than the OECD average, the correlation appears in bold; for those school systems where there is no apparent relationship, the cell in the table is coloured blue.

More is not always better

For students attending disadvantaged schools, quantity of resources does not necessarily translate into quality of resources. In general, more disadvantaged students attend schools with lower student-teacher ratios, but more advantaged students attend schools that have a higher proportion of teachers who have a university degree.

Findings from PISA suggest that many students face the double liability of coming from a disadvantaged background and attending a school with lower-quality teaching resources. Taking into account the size of the student population in schools, OECD countries allocate at least an equal, if not a larger, number of mathematics teachers to disadvantaged schools as to advantaged schools. As Figure II.4.6 shows, however, disadvantaged schools tend to have great difficulty in attracting qualified teachers. For example, in the Netherlands the proportion of qualified teachers in socio-economically advantaged schools is three times higher than the proportion of qualified teachers in disadvantaged schools (52% versus 14%), while the student-teacher ratio is 28% higher in socio-economically advantaged than in disadvantaged schools (18 versus 14 students per teacher, respectively). A similar situation is observed in Belgium, Croatia, Greece, Iceland, Italy, Kazakhstan, Luxembourg, Montenegro, the Russian Federation and Slovenia. In Austria, the student-teacher ratio in socio-economically advantaged schools is smaller and the proportion of university-educated teachers is higher than in disadvantaged schools. That is, disadvantaged schools have fewer teachers per student and those teachers tend to have had less education. A similar situation is observed in Romania, Shanghai-China and Uruguay.

Ensuring an equitable distribution of resources is still a major challenge for many countries, if not in terms of the quantity of resources, then in terms of their quality. As Figure II.4.7 shows, student socio-economic status and school socio-economic profile explain a significant proportion of the variation in teacher quality across schools. Between 17% and 27% of the variation in teacher quality across schools in Croatia, Liechtenstein, Luxembourg, the Netherlands and Slovenia is so explained, as is more than 35% of that variation in Austria and Belgium. Volume IV takes this analysis further by examining the inter-relationship between socio-economic status and resources, policies and practices in greater detail.

Challenging school environments

Disadvantaged schools often have poor disciplinary climates. As Figure II.4.8 shows, the differences in disciplinary climate between advantaged and disadvantaged schools are particularly marked in Croatia, Hungary, Shanghai-China and Slovenia, with a difference of more than half a unit on the *index of disciplinary climate*, while in Estonia, Jordan, Latvia, Norway, Peru and Thailand there are no apparent differences in disciplinary climate across schools related to the schools' socio-economic profile. As Figure II.4.9 shows, in some systems socio-economic status is strongly related to disciplinary climate while in others the relationship is much weaker. The variation across school systems in the strength of this relationship suggests that system- and school-level policies play a role in increasing or mitigating these differences.

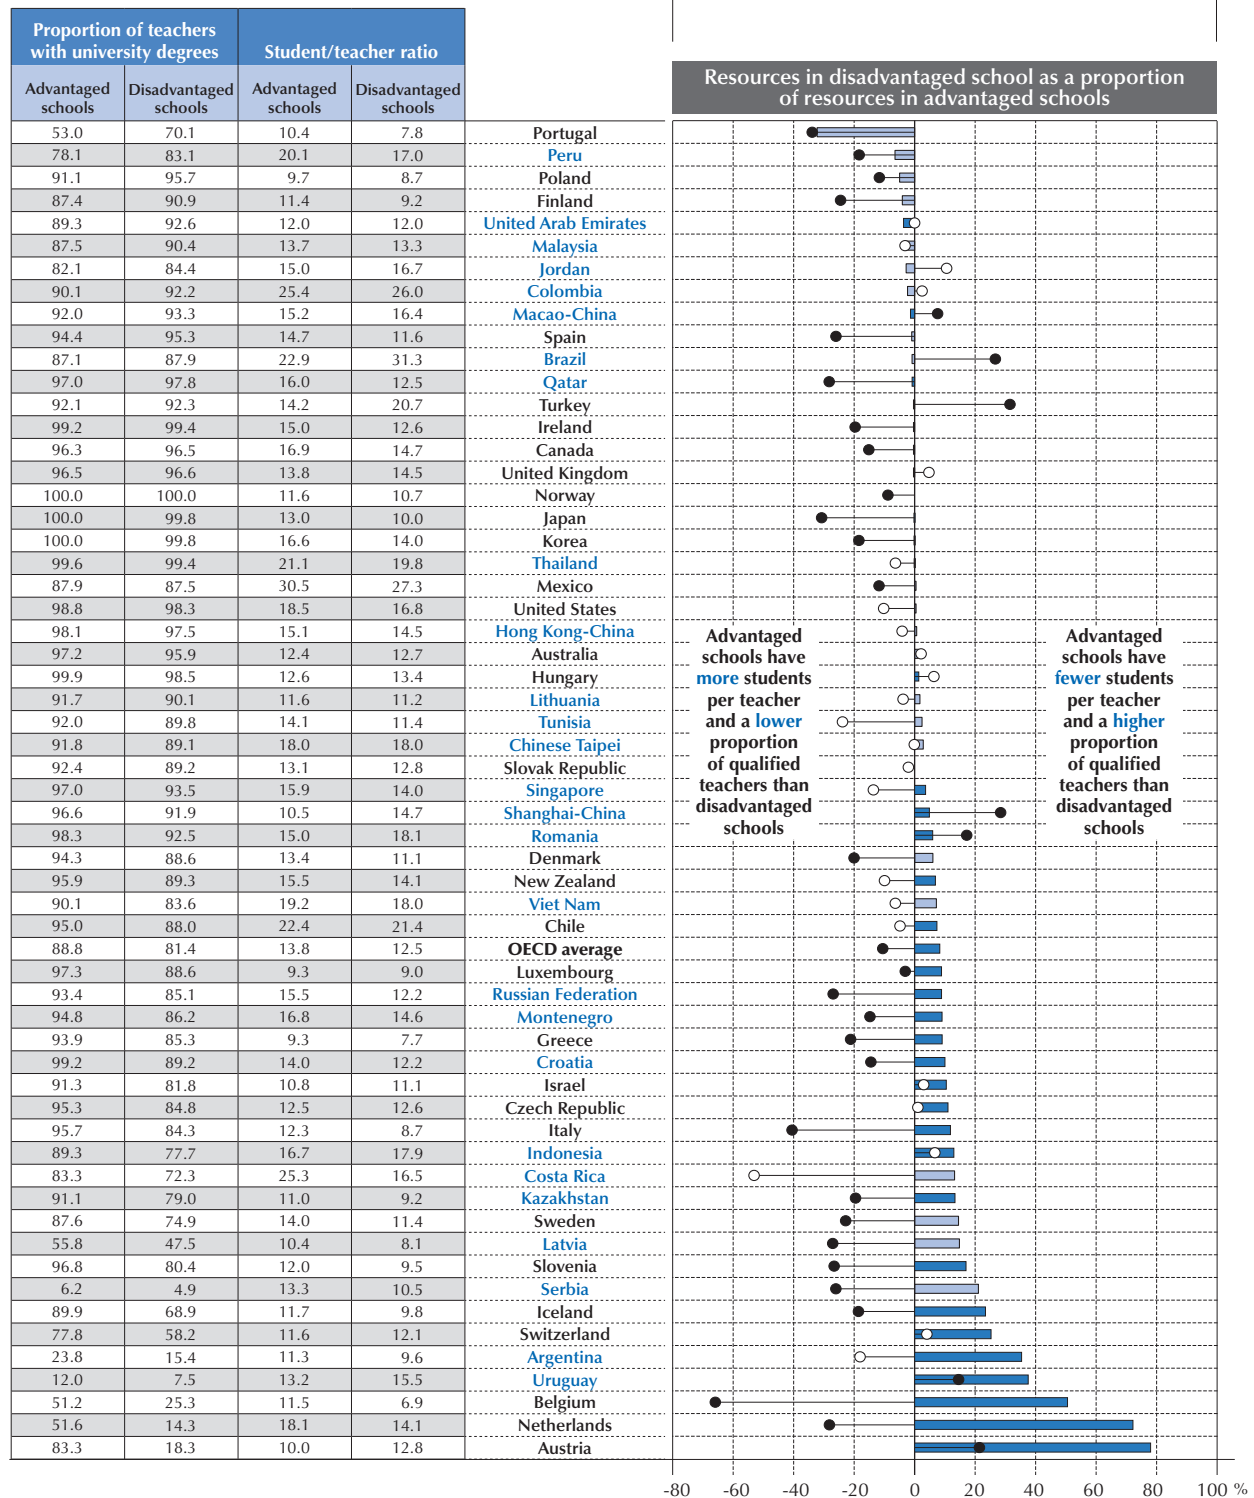

While all these factors may be more or less related to student performance, it is clear that they do not constitute the kind of supportive learning environments that disadvantaged students need. If schools are to compensate for resources and support that students are lacking at home, it is hard to imagine how these environments can enable disadvantaged students to reach their potential.

Learning opportunities outside school and parents' expectations of schools

Parents play a key role in their children's education in various ways, including by providing additional learning opportunities through after-school programmes or private tutoring to enhance or support learning at school, setting high expectations for their children and the school they attend, demanding that those expectations are met, and putting pressure on schools to achieve higher academic standards. In all of these areas, socio-economic status and resources at home are closely related.

■ Figure II.4.6 ■

Teacher quantity and quality, by schools' socio-economic profile

Note: Differences in resources between students in advantaged and disadvantaged schools that are statistically significant are marked in a darker tone. Countries and economies are ranked in ascending order of the proportion of qualified teachers in advantaged schools relative to the proportion of qualified teachers in disadvantaged schools.

StatLink <http://dx.doi.org/10.1787/888932964851>

In all countries/economies that participated in PISA 2012, socio-economically advantaged students tend to spend more hours after school doing homework or other study required by their teachers. The relationship between a student's socio-economic status and the time spent on homework (on all subjects) is relatively strong (a correlation above 0.3) in Belgium, Bulgaria, Hungary, Italy, Japan, Shanghai-China, Chinese Taipei and the United Kingdom. Socio-economically advantaged students tend to spend more time than disadvantaged students attending after-school classes organised by a commercial company and paid for by their parents and the relationship is particularly strong (with a correlation above 0.3) in Japan and Korea (Figure II.4.5).

Parents' aspirations for their child's education are also strongly related to socio-economic status. The parents of advantaged students have higher aspirations for their child's education than parents of disadvantaged students do. Advantaged parents also put greater pressure on schools to meet high academic standards. In all countries and economies (except Hong Kong-China, Indonesia, Liechtenstein, Luxembourg, Montenegro and Switzerland), more advantaged students attend schools whose principals reported that "there is constant pressure from many parents who expect our school to set very high academic standards and to have our students achieve them" (Figure II.4.5).

OPPORTUNITIES, RESOURCES, PERFORMANCE AND SOCIO-ECONOMIC STATUS

Student performance is related to socio-economic status, at both the school and the student levels, and to the resources and opportunities available to students and schools. Across OECD countries, 49% of the performance differences among students who attend different schools is accounted for by differences in access to opportunities and resources. The average difference in mathematics performance between more advantaged and less advantaged schools drops from 69 score points to 35 score points after taking these differences into account. Differences in opportunities and resources also account for 39% of the performance differences observed among students who attend the same school. Differences in disciplinary climate account for 17% of performance differences, and the quality of teachers accounts for 8% of performance differences (Table II.4.9). Figure II.4.10 shows the between-school difference in performance, before and after accounting for differences in opportunities to learn and educational resources across both students and schools for those countries with available data.⁵

Figure II.4.10

Performance differences related to differences in exposure to formal mathematics to learn and resources¹

Note: Score-point differences that are statistically significant are marked in a darker tone.

StatLink <http://dx.doi.org/10.1787/888932964851>

PARTICIPATION IN PRE-PRIMARY EDUCATION

Many of the inequities that exist within school systems are already present when students enter formal schooling and persist as students progress through school (Alexander, Entwisle and Olson, 1997; Downey, von Hippel and Broh, 2004). Because these inequities tend to grow when school is out of session, earlier entrance into the school system may help to reduce them. With earlier entrance into pre-primary education, students are better prepared to enter and succeed in formal schooling.

Figure II.4.11 shows the advantage in mathematics performance among students who reported having attended pre-primary education for more than one year over those who reported that they had not, both before and after accounting for students' socio-economic status. In all countries with available data, except Estonia and Latvia, students who had attended pre-primary education for more than one year outperformed students who had not. This finding remains unchanged after socio-economic status is accounted for in all countries with available data (except Estonia and Latvia). On average across OECD countries, the advantage amounts to more than 53 score points before accounting for socio-economic status, and to 31 points after accounting for socio-economic status. The difference between the two suggests that attendance in pre-primary education for more than one year is somewhat related to socio-economic status; still, there is a strong, independent relationship between having attended pre-primary school and performance at age 15. Those who did not participate in pre-primary education are 1.84 times more likely to score at the bottom of the performance distribution.

In France and the Slovak Republic, students who reported having attended pre-primary school for more than one year score at least 100 points higher in mathematics than students who had not attended pre-primary education. In France, only 2% of students had not participated in any pre-primary education, while 92% had attended for more than one year.

■ Figure II.4.11 ■

Differences in mathematics performance, by attendance at pre-primary school*Between students who attended pre-primary school for more than one year and those who had not attended*

Note: Score-point differences that are statistically significant are marked in a darker tone.

Countries and economies are ranked in descending order of the score-point difference in mathematics performance between students who reported that they had attended pre-primary school (ISCED 0) for more than one year and those who had not attended pre-primary school, after accounting for socio-economic status.

Source: OECD, PISA 2012 Database, Table II.4.12.

StatLink <http://dx.doi.org/10.1787/888932964851>

Those who had not participated are largely those from disadvantaged families. However, even after students' socio-economic status is accounted for, the strong relationship between attendance in pre-primary school and performance persists, although differences in performance are halved. The situation is similar in Shanghai-China, where the performance difference before accounting for socio-economic status is 118 score points but 72 points after taking socio-economic status into account. After accounting for socio-economic status, the score differences between students who had not attended pre-primary education and those who had attended for more than one year are largest (i.e. at least 50 score points) in the Czech Republic, France, Hong Kong-China, Italy, Macao-China, Qatar, Shanghai-China, the Slovak Republic and Switzerland. However, among this group of countries, the population relevance is less than 5% (the OECD average population relevance) in all countries except Shanghai-China (7%), the Slovak Republic (11%) and Qatar (17%) (Table II.4.12).

Figure II.4.12 highlights those countries where the participation rates are relatively low (the proportion of students who did not attend pre-primary school is high) and the relative risk of low performance for those who did not attend is particularly high. Indonesia and Turkey show high relative risk and very low participation rates. Croatia, Lithuania, Montenegro, Qatar and Tunisia also show low participation rates and relative risks that are relevant even if they are below the OECD average. In contrast, in France, Israel, Shanghai-China and the Slovak Republic, the relative risk is very high but few students are vulnerable to this type of risk.

In practically all countries, there is no significant difference in performance observed between advantaged and disadvantaged students when considering the relationship between pre-primary attendance and mathematics performance at age 15 (Table II.4.13). In 32 OECD countries and 22 partner countries and economies, disadvantaged and advantaged students benefit equally from pre-primary attendance. Across OECD countries, immigrant students who had attended pre-primary school score 14 points higher, on average, than immigrant students who had not attended (Table II.4.14).

Many other factors, apart from participation in pre-primary education, have an impact on 15-year-olds' performance in school, and the estimates provided here are limited because they do not take many of these other factors into account. Volume IV of this report explores these issues further and examines how they have evolved since PISA 2003. The trends show that equity issues related to pre-primary education are on the rise in many countries, and that disadvantaged students, those who would benefit most from pre-primary education, are still under-represented in pre-primary enrolments.

■ Figure II.4.12 ■

Pre-primary school, mathematics performance and students' socio-economic status

*Turkey and Indonesia have a large percentage of students who did not attend pre-primary (70% and 46%, respectively) and high relative risk, and Kazakhstan also has a high non-attendance rate (65%) but a lower-than-average relative risk. They are not included in this figure to make differences among other countries more visible.

Notes

1. For a more in-depth analysis of opportunity to learn in PISA 2012, see Schmidt et al. (2013).
2. Advantaged (disadvantaged) schools are those where the typical student in the school, or the socio-economic profile of the school, is above (below) the socio-economic status of the typical student in the country, the country mean socio-economic status. In each school, a random sample of 35 students are to take part in PISA (for more details see the *PISA 2012 Technical Report* [OECD, forthcoming]). The socio-economic profile of the school is calculated using the information provided by these students. Therefore, the precision of the estimate depends on the number of students that actually take the test in the school and the diversity of their answers. This precision was taken into account when classifying schools as advantaged, disadvantaged or average. If the difference between the school socio-economic profile and the socio-economic status of the typical student in the country (the mean socio-economic status at the country level) was not statistically significant, the school was classified as a school with an average socio-economic profile. If the school profile was statistically significantly above the country mean, the school is classified as a socio-economically advantaged school. If the profile was below the country mean, the school is classified as a socio-economically disadvantaged school.
3. These results also depend on how schools are defined and organised within countries, and by the units that were chosen for sampling purposes. For example, in some countries, some of the schools in the PISA sample were defined as administrative units (even if they spanned several geographically separate institutions, as in Italy); in others, they were defined as those parts of larger educational institutions that serve 15-year-olds; in others they were defined as physical school buildings; and in yet others they were defined from a management perspective (e.g., entities having a principal). The *PISA 2012 Technical Report* (OECD, forthcoming) provides an overview of how schools were defined. Because of the manner in which students were sampled, the within-school variation includes variation between classes as well as between students. In Slovenia, the primary sampling unit is defined as a group of students who follow the same study programme within a school (an educational track within a school). So in this particular case, the between-school variation is actually the difference between tracks within a school.
4. These are the results of a simple decomposition of the variation on a three-level model, with students nested within schools, and schools nested within countries. The results are based on the pooled sample of all the countries and economies that participated in PISA 2012.
5. All the models presented in Table II.4.9 include student and school level socio-economic status, then individual characteristics (gender, immigrant background and language at home) and school location are included. All of these variables are kept for every single model. School and student level variables measuring availability and quality of resources are introduced one group at a time. At the end, all variables are combined in a single model: the “combined model”. Some students, schools and countries do not have data for some of these variables, therefore they are not included on the combined model. Then a baseline model, only with student and school level socio-economic status is presented, where all students, schools and countries without data have been omitted, which allows a more direct comparison with the estimates in the combined model. Figure II.4.10 presents the results of these last two models, the combined model and the basic model with all missing observations deleted.

5

Policy Implications of Equity in Education

This chapter analyses the different measures of equity in education produced by PISA and considers various policy options for improving performance and equity in education outcomes and opportunities for all students.

Home background influences success in education, and schooling often reinforces that influence. Although poor performance in school does not automatically stem from socio-economic disadvantage, the socio-economic status of students and schools does appear to have a powerful influence on learning outcomes. Because advantaged families are better able to reinforce and enhance the effect of schools, because students from advantaged families attend higher-quality schools, or because schools are simply better-equipped to nurture and develop young people from advantaged backgrounds, in many countries schools tend to reproduce existing patterns of socio-economic advantage, rather than create a more equitable distribution of learning opportunities and outcomes.

Other characteristics of students, besides their socio-economic status, are closely related to performance in PISA. Family structure, parents' job status, immigrant background and the language spoken at home are not only associated with performance differences, they are also interlinked. For example, children of low-educated parents, who also tend to be disadvantaged, are likely to be among those students whose parents are not working. In some countries, adult immigrants may find it hard to find an occupation that matches their education and skills; thus they may end up in low-status occupations, which, in turn, will be translated into a more disadvantaged socio-economic status among immigrant students.

In short, socio-economic disadvantage is closely interconnected with many of the student and school characteristics that are associated with performance. It is often difficult to disentangle the impact of socio-economic status on performance from that of other factors. In drawing conclusions for education policy and practice from the results presented here, it is crucial to understand the interplay between all these factors.

In general, the results that emerge from this volume show large differences between countries in the extent to which socio-economic status influences learning outcomes, which suggests that it is indeed possible to attain high levels of equity in education even among high-performing countries and economies. Differences across countries in the extent to which student- and school-level factors are associated with performance and socio-economic status show that system- and school-level policies and practices have an impact on both equity and performance outcomes.

This volume highlights the importance of taking socio-economic status into account when analysing performance differences. For example, students from single-parent families tend to underperform when compared with students from other types of families; however in many countries and economies, the performance difference disappears once students' socio-economic status is taken into account. Another finding shows that schools with large populations of immigrant students tend to underperform. Yet once the socio-economic status of students and, crucially, the socio-economic profile of the schools themselves – a measure of the concentration of socio-economic disadvantage at the school level – is taken into account much, if not all, of the underperformance of these schools can be linked to the disadvantaged socio-economic status of their students, both immigrant and non-immigrant.

The allocation of resources across schools is also associated with equity in outcomes and opportunities. With some notable exceptions, OECD countries try to allocate at least an equal, if not a larger, number of teachers per student in disadvantaged schools as they do in advantaged schools. This said, disadvantaged schools still report great difficulties in attracting qualified teachers. In other words, in disadvantaged schools, more resources do not necessarily translate into better-quality resources. This finding suggests that many students face the double drawback of coming from a disadvantaged background and attending a school with lower-quality resources. Many countries also show a strong relationship between the socio-economic status of students and their success at school. In some of these countries, these disparities are magnified by large variations in the socio-economic profile of schools' student populations.

This volume also presents evidence of the close relationship between education opportunities, as measured by students' reports on their exposure to and familiarity with formal mathematics, and students' socio-economic status and performance. Some education systems tend to separate students, either across classes or schools, according to their performance. Evidence from PISA shows that school systems that segregate students across schools according to their performance also tend to be those where students are segregated by socio-economic status and exposure to formal mathematics. That in some school systems disadvantaged students have less exposure to and familiarity with basic mathematic concepts suggests that these systems need to do more to address the academic needs of these students before they reach the end of compulsory education.

In Finland, early detection mechanisms, such as periodic individualised assessments of students by several groups of teachers, and special education opportunities enable educators to identify specific subject areas that students struggle to learn. Struggling students are then offered the necessary support early on in their schooling, before they become stuck

and cannot continue their education at the same pace as their peers. By contrast, in other systems, students are retained and keep receiving the same inadequate opportunities to learn until the system can no longer keep them behind. Israel (see Box IV.1.4) and Germany (Box II.3.2) have designed programmes that offer more learning opportunities to immigrant and minority students by providing a longer school day (Germany) or encouraging students to participate in smaller study groups (Israel).

The analyses pertaining to school effectiveness presented in this report are based on data describing school offerings at the late-primary or secondary levels. However, an assessment such as PISA provides an indication of students' cumulative learning such that a country's results in PISA, or in any assessment for that matter, depend on the quality of care and stimulation provided to children during infancy and their pre-school years, as well as on the opportunities children have to learn, both in school and at home, during their elementary and secondary school years.

Improving quality and equity thus requires a long-term view and a broad perspective. For some countries, this may mean safeguarding the healthy development of young children or improving early childhood education. For others, it may mean socio-economic reforms that enable families to provide better care for their children. And in many countries, it may mean greater efforts to increase socio-economic inclusion and improve school offerings.

PATTERNS IN THE RELATIONSHIP BETWEEN PERFORMANCE AND SOCIO-ECONOMIC STATUS

Australia, Canada, Estonia, Finland, Hong Kong-China, Japan, Korea, Liechtenstein and Macao-China show above-OECD-average mean performance and a weak relationship between socio-economic status and student performance (the strength of the socio-economic gradient). In Viet Nam, the strength of this relationship is around average while performance differences associated with socio-economic disparities (the slope of the socio-economic gradient) are below average (Figure II.5.1a). These countries combine high average performance with equity, demonstrating that the two are not mutually exclusive.

While the focus here is on socio-economic context, many of these countries also achieve greater levels of equity in other respects. Socio-economic disadvantage is, in many cases, a proxy for other sources of disadvantage. But this is not always the case. For example, in Finland, where differences in performance between advantaged and disadvantaged students are small, immigrant students underperform when compared to other students – and by a relatively large margin – even after accounting for socio-economic status. In Poland, rural schools perform well below urban schools, regardless of the schools' socio-economic profile.

Low performing students – those who do not reach a baseline level of performance (Level 2 in the PISA mathematics scale) – are at risk of later failing to integrate successfully into the labour market and into society more generally. Equity cannot be achieved where significant proportions of students fall behind. The same applies where a large proportion of 15-year-olds are not in school.

How can the impact of social background be moderated so that all students can realise their potential? The relationships between home background and performance described in this volume are manifested in very different patterns across different countries; thus, strategies for improvement need to be tailored accordingly. Figures II.5.1a and b show the key characteristics of the relationship between students' and schools' socio-economic profile and performance across education systems.

Figures II.5.2 to II.5.13 show the average performance and the socio-economic composition of the student population for each school in the countries/economies that participated in PISA 2012. As elsewhere in this volume, the socio-economic composition of a school is measured by the mean *PISA index of economic, social and cultural status* of the students who attend the school. Each circle in these figures represents one school, with the size of the circle proportional to the number of 15-year-olds enrolled in that school. The patterns show the extent to which students are segregated across schools according to their performance or socio-economic status. The figures show the overall performance differences across socio-economic groups, or the gradient between performance and socio-economic status, represented by the thin black line. The figures also present the average performance differences among schools with different socio-economic profiles – the between-school gradient, represented by the grey line, and the average within-school gradient, represented by the blue line. Schools above the between-school gradient (grey line) perform better than predicted by the socio-economic status of their students; schools below the between-school gradient perform worse than predicted by the socio-economic status of their students.

■ Figure II.5.1a ■

Summary of PISA measures of equity in education

			Higher quality or equity than the OECD average	Not statistically different from the OECD average	Lower quality or equity than the OECD average
	Average student performance	Percentage of students performing below Level 2	Strength of the relationship between student performance and socio-economic status	Performance differences across socio-economic status: slope of the socio-economic gradient	Length of the projection of the gradient line
			Percentage of explained variation in student performance	Score-point difference associated with a one-unit increase in socio-economic status	Difference between 95th and 5th percentile of socio-economic status
OECD average	494	23.1	14.6	39	2.83
Shanghai-China	613	3.8	15.1	41	3.00
Singapore	573	8.3	14.4	44	2.98
Hong Kong-China	561	8.6	7.5	27	3.10

1. Two-level regression of mathematics performance on student-level PISA index of economic, social and cultural status (ESCS) and school mean ESCS; within-school slope for ESCS and student-level variation explained by the model.

2. Two-level regression of mathematics performance on student ESCS and school mean ESCS; between-school slope of ESCS and school-level variation explained by the model.

3. Difference between the top and bottom quartiles calculated at the school level.

4. Also referred to as the index of social inclusion is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of socio-economic status, i.e. the variation in the PISA index of social, economic and cultural status of students between schools, divided by the sum of the variation in students' socio-economic status between schools and the variance in students' socio-economic status within schools.

5. Also referred to as the index of academic inclusion, which is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of performance, i.e. the variation in student performance between schools, divided by the sum of the variation in student performance between schools and the variation in student performance within schools.

Countries and economies are ranked in descending order of the average mathematics performance.

StatLink  <http://dx.doi.org/10.1787/888932964870>

The figures summarise the three levels at which the relationship between student background and performance manifests itself. One is the strength of the relationship between student performance and socio-economic status in a given country, as measured by how much of the variation in student performance can be attributed to variations in socio-economic status. The second shows the degree to which the variation in average performance among schools can be attributed to the variation in the average socio-economic status of the schools' student populations. The third reflects the relationship between student performance and socio-economic status within a given school: how much of the variation in student performance within a given school can be attributed to variations in socio-economic status within that particular school. The amount of socio-economic variation and the overall performance differences within a country are also relevant. While these figures do not capture all of the inequities that may be observed within countries, they can provide a reliable indication of equity in education opportunities, particularly from an international perspective.

Analysing these patterns can help policy makers in designing policies to improve equity in education opportunities (Willms, 2006). Some options, which can be considered in combination, include:

- **Targeting low performance, regardless of students' background, either by targeting low-performing schools or low-performing students within schools, depending on the extent to which low performance is concentrated by school.** Where between-school differences in performance are relatively large, interventions may be targeted at low-performing schools; where they are relatively small, interventions can be directed at low-performing students in each school. Such policies often tend to provide a specialised curriculum or additional instructional resources for particular students based on their level of academic achievement. For example, some school systems provide early-prevention programmes that target children who are deemed to be at risk of failure at school when they enter early childhood programmes or schools, while other systems provide late-prevention or recovery programmes for children who fail to progress at a normal rate during the first few years of primary school. Some performance-targeted programmes aim to provide a modified curriculum for high-achieving students, such as programmes for gifted students. Grade repetition is also sometimes considered a performance-targeted policy, because the decision to have a student repeat a grade is usually based on school performance. However, in many cases, grade repetition does not entail a modified curriculum or additional instructional resources; therefore, it does not fit the definition of a performance-targeted policy used here. In fact, as Volume IV of this report shows, grade repetition is a costly option that is rarely advisable when designing policies for higher performance and greater equity. The focus of performance-targeted policies tends to be at the lower end of the performance scale, regardless of the students' socio-economic status, and their objective is to bring low-performing students up to par with their peers. This volume and Volume IV of this report describe how countries such as Colombia (Box IV.4.3), Mexico (Box II.2.4) and Poland (Box IV.2.1), for example, have improved the information infrastructure of their education systems so that they can better identify and support struggling students and schools.
- **Targeting disadvantaged children through a specialised curriculum, additional instructional resources or economic assistance for these students.** A relatively strong social gradient, which accounts for a substantial proportion of performance variation, can indicate the relevance of such policies. Again, policies can be designed either at the school or individual level, depending on the strength of the inter-school social gradient and the extent to which schools are segregated by socio-economic status. Some approaches select students on the basis of a risk factor other than socio-economic status, such as whether the students are recent immigrants, members of an ethnic minority, or living in a rural or low-income community. The important distinction is that these programmes select students based on the families' socio-economic status rather than on the students' cognitive ability. As mentioned in Boxes II.3.2 and IV.1.4, countries such as Germany and Israel are indeed targeting students with an immigrant background or schools in small and rural communities. While not tackling socio-economic disadvantage per se, because of the close interconnection among different sources of disadvantage, these policies address inequities in a broad sense. While policies targeting disadvantaged children can aim at improving these students' performance in school, they can also be used to provide additional economic resources to these students. The emphasis here is on improving the economic circumstances of students from poor families, rather than offering specialised curricula or additional educational resources. Good examples of these kinds of policies are conditional cash transfers, as implemented in Brazil, Colombia and Mexico, through which parents receive funds if their children attend school. Providing free transportation and free lunch programmes for students from poor families is an example. More generally, providing transfer payments to poor families is one of the primary policy levers at the national level. The distinction between these kinds of compensatory policies and socio-economically targeted policies is not always clear-cut. For example, some jurisdictions have compensatory funding formulas that allocate funds for education to schools based on their students' socio-economic profile. In some sense this is a compensatory policy, but it could also be considered a socio-economically targeted policy since the intention is to provide additional educational resources to students from disadvantaged backgrounds.

As described in the different volumes of this report, countries such as Brazil (see Box I.2.4), Germany (Box II.3.2), Israel (see Box IV.1.4), Mexico (Box II.2.4) and Turkey (see Box I.2.5) and have already implemented targeted policies to improve the performance of low-achieving schools or students, or have distributed more resources to those regions and schools that need them most.

- Applying more universal policies to raise standards for all students.** These types of policies are likely to be most relevant in countries with weaker gradients and less variation in student performance. They can involve altering the content and pace of the curriculum, improving instructional techniques, introducing full-day schooling, changing the age of entry into school, or increasing the time spent in classes. Some countries, such as Denmark and Germany, responded to PISA 2000 results by introducing major school and curricular reforms that included some of these changes. There have also been efforts to increase parents' engagement, including by encouraging greater involvement at home and more participation in school governance. Many universal policies are directed at changing teacher practices, or they aim to increase the accountability of schools and school systems by assessing student performance. As described in this and other volumes of this report, some countries have introduced system-wide reforms that are aimed at moving towards more comprehensive schooling (Poland) or less tracking (Germany). These reforms simultaneously address various sources of inequity, such as a socio-economically disadvantaged background, immigrant status or a challenging family structure. Some countries are focusing on improving the overall quality of educational resources – including by recruiting and hiring high-quality teachers – and making them available to all schools, particularly disadvantaged schools. Countries that have improved their performance in PISA, like Brazil (see Box I.2.4), Colombia (see Box IV.4.3), Estonia (see Box I.5.1), Israel (see Box IV.1.4), Japan (see Box III.3.1) and Poland (see Box IV.2.1), for example, have established policies to improve the quality of their teaching staff by adding to the requirements to earn a teaching license, providing incentives for high-achieving students to enter the profession, increasing salaries to make the profession more attractive and to retain more teachers, or by offering incentives for teachers to engage in in-service teacher-training programmes.
- Including marginalised students in mainstream schools and classrooms.** Inclusive practices often concentrate on including students with disabilities in regular classrooms, rather than segregating them in special classes or schools. This volume considers inclusive policies as those that aim to include students who may be segregated, for example by socio-economic disadvantage. Some inclusive policies try to reduce between-school socio-economic segregation by redrawing school-catchment boundaries, amalgamating schools, or by creating magnet schools in low-income areas. As discussed in Volume IV of this report, many school systems are highly stratified. In these systems, there may be more incentives for schools to select the best students, and fewer incentives to work with difficult students if there is an option of transferring them to other schools. Some of the school systems that have improved in performance and equity in recent years are becoming more inclusive. For example, Poland (see Box IV.2.1) reformed its education system by delaying the age of selection into different programmes; and schools in Germany (Box II.3.2) are also moving towards reducing the levels of stratification across education programmes.

The rest of this chapter describes various policy options available to countries, depending on how student performance is related to the social context of students and schools. If the proportion of low-performing students is large, then policy interventions should target these students. Box II.5.1 offers guidance on designing policies to improve performance and equity in other cases. For example, universal policies are most beneficial for countries shown in the top-left quadrant. Policies that target socio-economic disadvantage may be more effective for the countries shown in the right quadrants, while policies that target low performance may be more effective for countries shown in the bottom quadrants.

Box II.5.1. **A framework of policies to improve performance and equity in education**

This volume identifies two main measures of equity in education outcomes: the strength of the relationship between performance and socio-economic status (the strength of the socio-economic gradient) and the size of performance differences across socio-economic groups (the slope of the socio-economic gradient). The following typology describes countries based on their mean performance and depending on whether they score above or below the OECD average in these measures.

...

		Performance differences across socio-economic groups (slope of the socio-economic gradient)		
		Below OECD average: <i>Flat</i> socio-economic gradient	Average	Above OECD average: <i>Steep</i> socio-economic gradient
Strength of the relationship between performance and socio-economic status: (strength of the socio-economic gradient)	Below OECD average: <i>Weak</i> socio-economic gradient	Canada Estonia Finland Hong Kong-China Iceland <i>Italy</i> <i>Jordan</i> <i>Kazakhstan</i> Macao-China Mexico <i>Montenegro</i> Norway <i>Qatar</i> <i>Thailand</i> <i>United Arab Emirates</i>	Japan Korea Liechtenstein <i>Serbia</i> <i>Sweden</i>	Australia
	Average	<i>Argentina</i> <i>Brazil</i> <i>Colombia</i> <i>Greece</i> <i>Indonesia</i> <i>Malaysia</i> <i>Spain</i> <i>Tunisia</i> <i>Turkey</i> <i>United States</i> Viet Nam	<i>Croatia</i> Denmark Germany Ireland <i>Latvia</i> <i>Lithuania</i> Netherlands Poland <i>Romania</i> <i>Russian Federation</i> Shanghai-China Slovenia Switzerland United Kingdom	Austria Belgium Czech Republic <i>Israel</i> Singapore
	Above OECD average: <i>Strong</i> socio-economic gradient	<i>Chile</i> <i>Costa Rica</i> <i>Peru</i> Portugal	<i>Bulgaria</i> <i>Luxembourg</i> <i>Uruguay</i>	Chinese Taipei France <i>Hungary</i> New Zealand <i>Slovak Republic</i>

Notes: Countries and economies with mean mathematics performance above the OECD average are shown in **bold**.

Countries and economies with mean mathematics performance below the OECD average are shown in *italics*.

Considering these two dimensions of equity in education and the policy options described above can help policy makers map a way forward to raise quality and improve equity.

Performance differences across the socio-economic spectrum are:		
	Small: Flat gradient	Large: Steep gradient
Impact of socio-economic status on performance is weak	When performance differences across the socio-economic spectrum are small and students often perform better (or worse) than expected, given their socio-economic status, one of the main policy goals is to improve performance across the board. In these cases, universal policies tend to be most effective. These types of policies include changing curricula or instructional systems and/or improving the quality of the teaching staff, e.g. by requiring more qualifications to earn a teaching license, providing incentives for high-achieving students to enter the profession, increasing salaries to make the profession more attractive and to retain more teachers, and/or offering incentives for teachers to engage in in-service teacher-training programmes.	When performance differences across the socio-economic spectrum are large and students often perform better (or worse) than expected given their socio-economic status, one of the main policy goals is to improve performance among the lowest performers, regardless of their socio-economic status. In these cases, targeting disadvantaged students only would provide extra support to some students who are already performing relatively well, while it would leave out some students who are not necessarily disadvantaged but who perform poorly. Policies can be targeted to low-performing students if these students can be easily identified, or to low-performing schools, particularly if low performance is concentrated in particular schools. Examples of such policies involve evaluation, feedback and appraisals for students, teachers and schools, or establishing early-warning mechanisms and providing a modified curriculum or additional instructional support for struggling students.
Impact of socio-economic status on performance is strong	When performance differences across the socio-economic spectrum are small but students perform as expected, given their socio-economic status, one of the main policy goals is to dismantle the barriers to high performance associated with socio-economic disadvantage. In these cases, effective compensatory policies target disadvantaged students or schools, providing them with additional support, resources or assistance. Free lunch programmes or free textbooks for disadvantaged families are other examples.	When performance differences across the socio-economic spectrum are large and students perform as would be expected, given their socio-economic status, one of the main policy goals is to reduce performance differences and improve performance particularly among disadvantaged students. A combination of policies targeting low performance and socio-economic disadvantage tend to be most effective in these cases, since universal policies may be less effective in improving both equity and performance simultaneously.

...

Another important aspect to consider is whether these policies target students or schools. In many cases, it may not be cost-effective to target individual students who are struggling in a particular subject area or who are facing a particularly challenging situation in or outside of school. The evidence collected in PISA can provide some indication as to when school- or student-level interventions would prove more effective. Two indicators offer guidance in this respect: the extent of between-school differences in socio-economic profiles, and the relationship between a school's socio-economic profile and its mean performance.

Where few differences are observed across schools, targeting students within schools is an option. By contrast, if large performance or socio-economic differences are observed between schools, then targeting specific schools – for example, low-performing or socio-economically disadvantaged schools – becomes a possibility. Targeting socio-economically disadvantaged schools may prove effective where there are large performance differences across schools related to socio-economic status.

A DISPROPORTIONATE NUMBER OF LOW-PERFORMING STUDENTS

Where many students score below the baseline level of proficiency, policies that target low-performing students may be more effective, regardless of those countries'/economies' level of equity in education. The proportion of students who score below proficiency Level 2 in mathematics is particularly large – more than 40% – in Albania, Argentina, Brazil, Bulgaria, Chile, Colombia, Costa Rica, Indonesia, Jordan, Kazakhstan, Malaysia, Mexico, Montenegro, Peru, Qatar, Romania, Thailand, Tunisia, Turkey, the United Arab Emirates and Uruguay (Figure II.5.1). In these countries, socio-economic status is not strongly related to performance (except in Bulgaria, Chile, Costa Rica, Peru and Uruguay), and performance differences across socio-economic groups are below the OECD average (except in Bulgaria, Romania and Uruguay, where they are at the OECD average). Performance is generally poor and there is little variation in performance among students, even though differences in socio-economic status may be considerable. In all these countries, the range of socio-economic status (the difference in socio-economic status between the top and bottom 5% of students) is above the OECD average (except in Kazakhstan, where it is below average, and Montenegro and the United Arab Emirates, where it is average). In addition, in many of these countries, there are many 15-year-olds who are not enrolled in school and who did not participate in the PISA assessment. Because this population is likely to be socio-economically disadvantaged, the students in these countries and economies appear as a more homogeneous population than the entire group of 15-year-olds. In some of these countries, the PISA measures of socio-economic status may not discriminate sufficiently among levels of disadvantage. Figure II.5.2 contrasts the profiles of some of these countries.

Some countries in this group, like Brazil, Colombia and Mexico, have implemented policies targeting socio-economically disadvantaged students. The fairly small proportion of variation in student performance that is explained by socio-economic status suggests that poor performance deserves as much attention as socio-economic disadvantage.

DIFFERENT SLOPES AND STRENGTHS OF SOCIO-ECONOMIC GRADIENTS

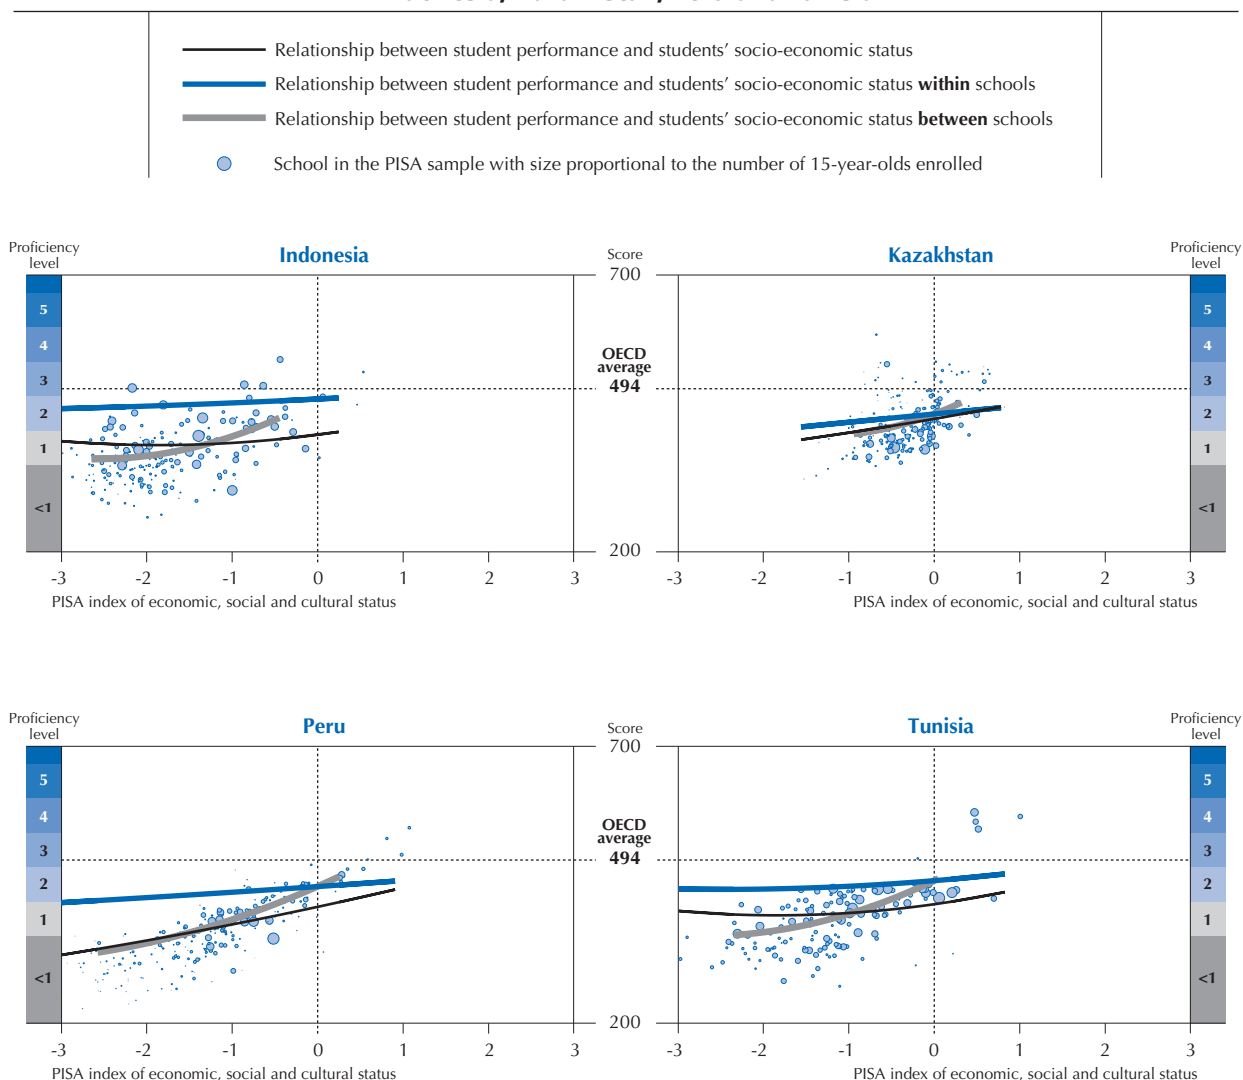

School administrators often wonder whether efforts to improve student performance should be targeted mainly at those students who perform poorly or those from socio-economically disadvantaged backgrounds. Performance differences across the socio-economic spectrum, together with the proportion of performance variation explained by socio-economic status, are useful indicators for answering this question. There is an important distinction between the slope of the social gradient, which refers to the average size of the performance gap associated with a given difference in socio-economic status, and its strength, which is associated with how closely students conform to predictions of performance based on their socio-economic status.

In countries with relatively flat gradients, i.e. where performance differences related to socio-economic status are small, policies that specifically target students from disadvantaged backgrounds would not, by themselves, address the needs of many of the country's low-performing students.

■ Figure II.5.2 ■

Relationship between school performance and schools' socio-economic profile in countries that have large proportions of students performing below Level 2: Indonesia, Kazakhstan, Peru and Tunisia

StatLink <http://dx.doi.org/10.1787/888932964984>

Universal policies for countries where performance differences are small and there is a weak relationship between performance and socio-economic status

Canada, Estonia, Finland, Hong Kong-China and Macao-China are the only school systems that participated in PISA 2012 that share above-average performance and above-average equity, whether measured by the strength of the relationship between socio-economic status and performance or the size of the performance differences across socio-economic groups (Figure II.5.1a). Within this group, even large differences in students' socio-economic status (such as those observed in Hong Kong-China and Macao-China, where the length of the gradient is above the OECD average) are, on average, not associated with large performance differences among students. In general, universal policies that reach all students are more likely to help these countries improve their performance and maintain above-average levels of equity in education outcomes. Japan, Korea and Liechtenstein also share above-average performance and a weak relationship between socio-economic status and performance, but performance differences across socio-economic

status are around average. Beyond universal policies, these countries may consider policies targeted to low performers who may not necessarily be defined by their socio-economic status (for example, immigrant students in Finland), or to poor-performing schools, when differences between schools are very large. In no high-performing country is the socio-economic gradient flat and strong.

■ Figure II.5.3 ■

Relationship between school performance and schools' socio-economic profile in countries with high performance and flat and weak gradients: Canada and Viet Nam

Source: OECD, PISA 2012 Database.

StatLink  <http://dx.doi.org/10.1787/888932965003>

Among countries whose mean performance is below or around the OECD average, greater equity in outcomes implies that all students perform equally well – or poorly – regardless of their background or that there are small differences in performance between advantaged and disadvantaged students. Iceland and Norway show average performance and high equity. Among OECD countries, Italy and Mexico show below-OECD-average performance and high equity; however some 25% of students in Italy and 55% of students in Mexico are low performers. Among the partner countries, Jordan, Kazakhstan, Montenegro, Qatar, Thailand and the United Arab Emirates all share high levels of equity and large proportions of students who perform below the baseline level of performance. In Greece, Spain, the United States and Viet Nam, performance differences related to socio-economic status (the slope of the gradient) are also below average, but the relationship between socio-economic status and performance (the strength of the gradient) is close to the OECD average. While Argentina, Brazil, Colombia, Indonesia, Malaysia, Tunisia and Turkey share this profile, in all of these countries more than 40% of students are low performers.

These data suggest that in many of these countries, a relatively smaller proportion of low-performing students come from disadvantaged backgrounds, and the relationship between performance and socio-economic status is weak. Thus, by themselves, policies that specifically target students from disadvantaged backgrounds would not address the needs of many of the country's lower-performing students. As is true in high-performing countries, in these countries, universal policies that reach all students and schools are likely to have more of an impact in improving performance while maintaining high levels of equity.

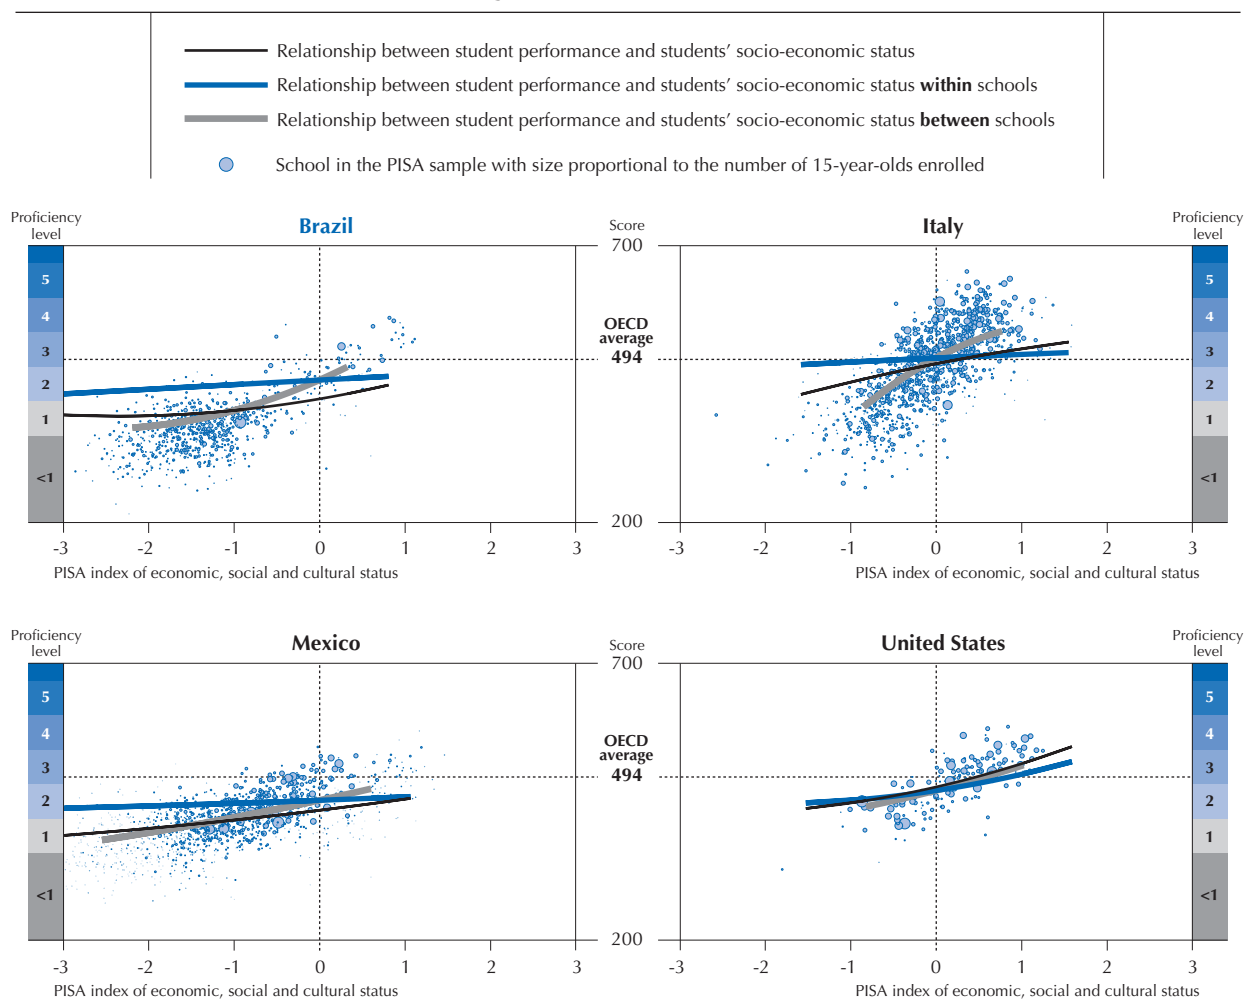

By contrast, targeting low achievers may prove more effective than targeting disadvantaged students. For example, if the goal is to ensure that most students achieve a minimum level of performance, policies that target disadvantaged students would be providing services to a sizeable proportion of students who already perform well. Where large proportions of students perform below the baseline level, policies targeting these students may be needed in order to ensure they are

not left behind. Among countries that perform below the OECD average, the proportion of students who score below the baseline level differs widely. In some countries, like Italy, the proportion is close to the OECD average, while in others, such as Argentina, Brazil, Colombia, Indonesia, Malaysia, Tunisia and Turkey, the proportion of students below the baseline level ranges from 42% in Turkey to 76% in Indonesia. Where the proportion of students who score below the baseline level is large, it is necessary to target these students and the schools they attend.

StatLink <http://dx.doi.org/10.1787/888932965022>

Policies that target socio-economic disadvantage for those countries where there are small performance differences and a strong relationship between performance and socio-economic status

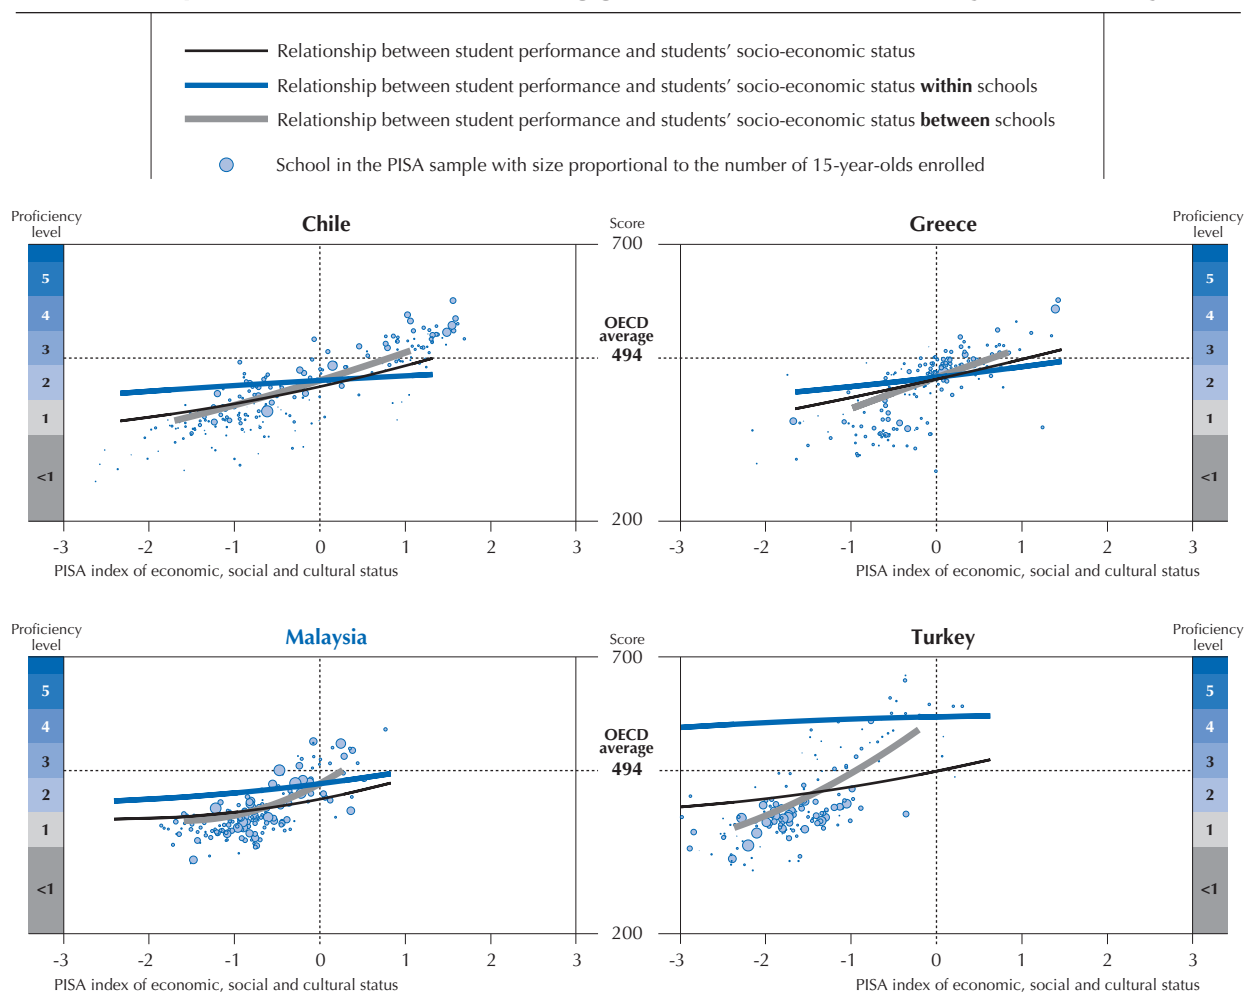

When the socio-economic gradient is flat but strong, meaning that performance differences related to socio-economic status are small, but there is a close relationship between socio-economic status and performance, a combination of universal policies and policies targeting disadvantaged students and schools may be most effective. One way of addressing the strong relationship between socio-economic status and performance is to add more flexibility to education systems, such as by offering pathways across programmes in tracked systems; another is to provide more and better resources and opportunities to disadvantaged students. Certain universal policies, such as increasing the amount or quality of the

time students spend at school, can also improve equity because they are likely to have a larger impact on disadvantaged students. Chile, Costa Rica, Peru and Portugal are the only countries where the socio-economic gradient is flat and strong. More than 40% of students in all of these countries, except Portugal, perform below the baseline proficiency level in mathematics. Policies that target low-performing students and schools, as well as universal policies to improve performance across the board, may be most effective in these countries.

■ Figure II.5.5 ■

Relationship between school performance and schools' socio-economic profile with average or low performance and flat and strong gradients: Chile, Greece, Malaysia and Turkey

StatLink <http://dx.doi.org/10.1787/888932965041>

Policies that target both performance and socio-economic disadvantage for countries where there are large performance differences and a strong relationship between performance and socio-economic status

In countries where performance differences across socio-economic groups are very large (a steep gradient), policies that target disadvantaged students are likely to be more effective, particularly if the strength of the relationship between performance and socio-economic status is also above average.

New Zealand and Chinese Taipei are the only two high-performing countries/economies with below-average levels of equity in education outcomes. Targeting low-performing and/or disadvantaged students is a policy option for both of these countries, as the steepness of the gradient suggests that low-performing students could rapidly improve their

performance if their socio-economic status also improved. The stronger-than-average relationship between socio-economic status and performance, however, suggests that in these countries very few students overcome the barriers to high performance that are linked with socio-economic status. Therefore, these countries also need to provide greater opportunities for socio-economically disadvantaged students to achieve higher performance. A combination of policies to improve equity while maintaining high levels of performance at the system level appears to be the most advisable course of action for these countries.

Austria, Belgium and Singapore also share high performance and large performance differences across socio-economic groups, but the strength of the relationship between performance and socio-economic status is only average. To address those large differences, these countries can focus on compensatory policies that support disadvantaged students and schools so that they are given as many opportunities and resources as their more advantaged peers.

■ Figure II.5.6 ■

Relationship between school performance and schools' socio-economic profile in countries with high performance and steep and strong gradients: Germany and New Zealand

Source: OECD, PISA 2012 Database.
StatLink <http://dx.doi.org/10.1787/888932965060>

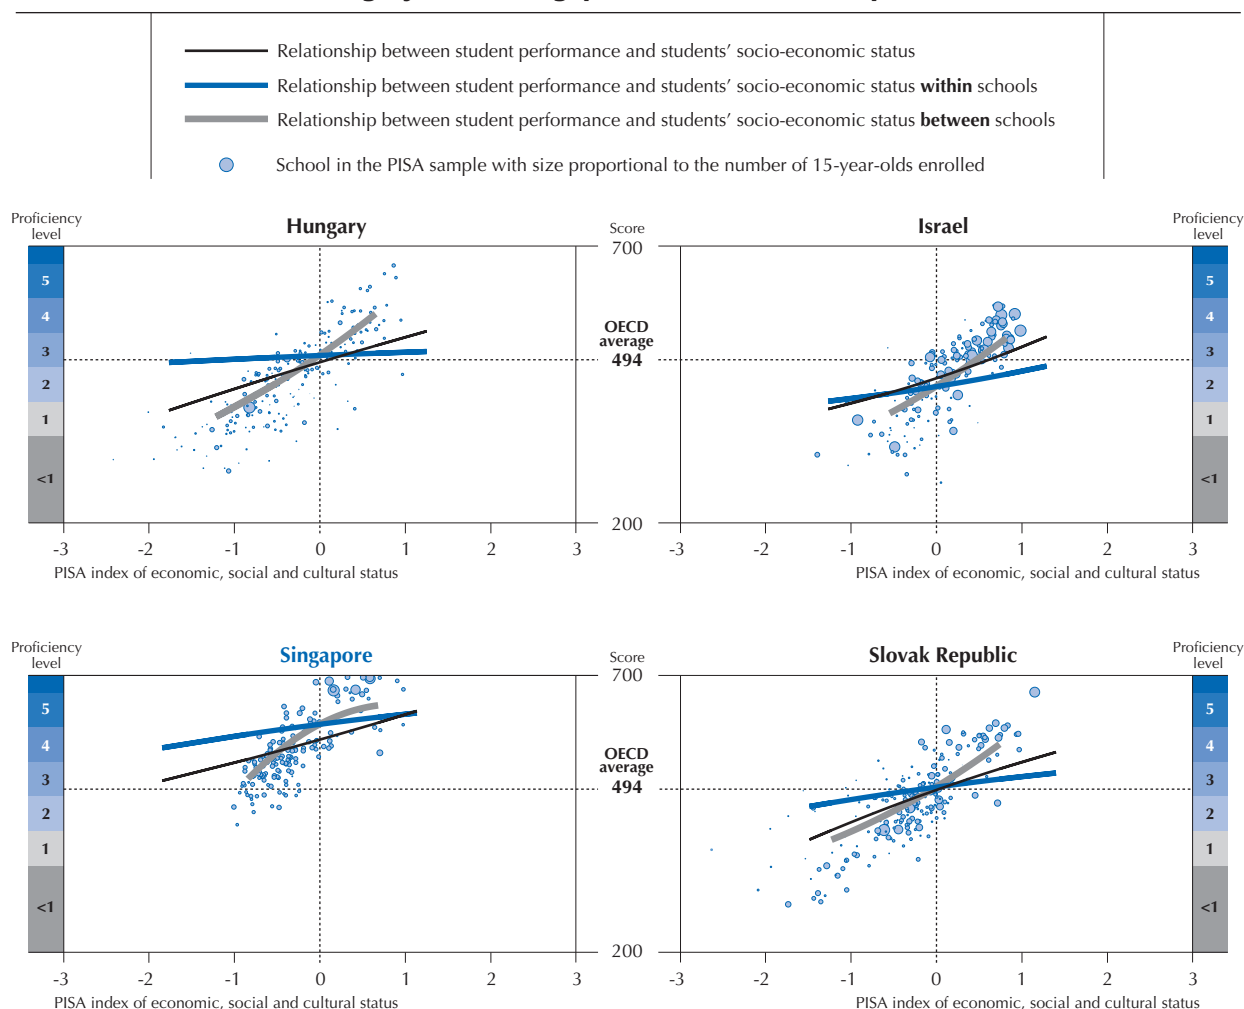

Where both poor performance and low equity are observed, such as in Hungary and the Slovak Republic, policies that target both performance and socio-economic disadvantage may prove effective in reaching those who need support the most – who, in these cases, are often the same students. The steep slope suggests that performance improves quickly as socio-economic status improves. However, the strong relationship between socio-economic status and performance suggests that few students perform better than what can be expected given their socio-economic status. Reforms that add flexibility to school systems, so that disadvantaged and poor-performing students have access to better resources and/or more and better opportunities to learn, can also help. Bulgaria, Luxembourg and Uruguay share this profile, although differences in performance related to socio-economic status are average, which suggests that universal policies aimed at improving the performance of all students may also be effective.

For countries where the impact of socio-economic status on performance is high (a steep slope), but only part of the variation in performance is explained by socio-economic status (a weak socio-economic gradient), policies that target disadvantaged students may not be as effective. In these countries, there tends to be a sizeable group of poor-performing students who are not disadvantaged. Among the high-performing countries, Australia is the only country participating in PISA 2012 with a weak relationship between socio-status and above-average performance differences across socio-economic groups.

Figure II.5.7

Relationship between school performance and schools' socio-economic profile in countries with low performance and steep and strong gradients: Hungary, Israel, Singapore and the Slovak Republic

Source: OECD, PISA 2012 Database.

StatLink <http://dx.doi.org/10.1787/888932965079>

These large differences suggest that targeting disadvantaged students and schools may help Austria improve equity while maintaining high performance. Viet Nam is the only high-performing country where there are small performance differences related to socio-economic status and where the strength of the relationship between performance and socio-economic status is around average. In this case, policies that target low-performing students and schools may help improve equity while maintaining high levels of performance.

LARGE SOCIO-ECONOMIC DISPARITIES

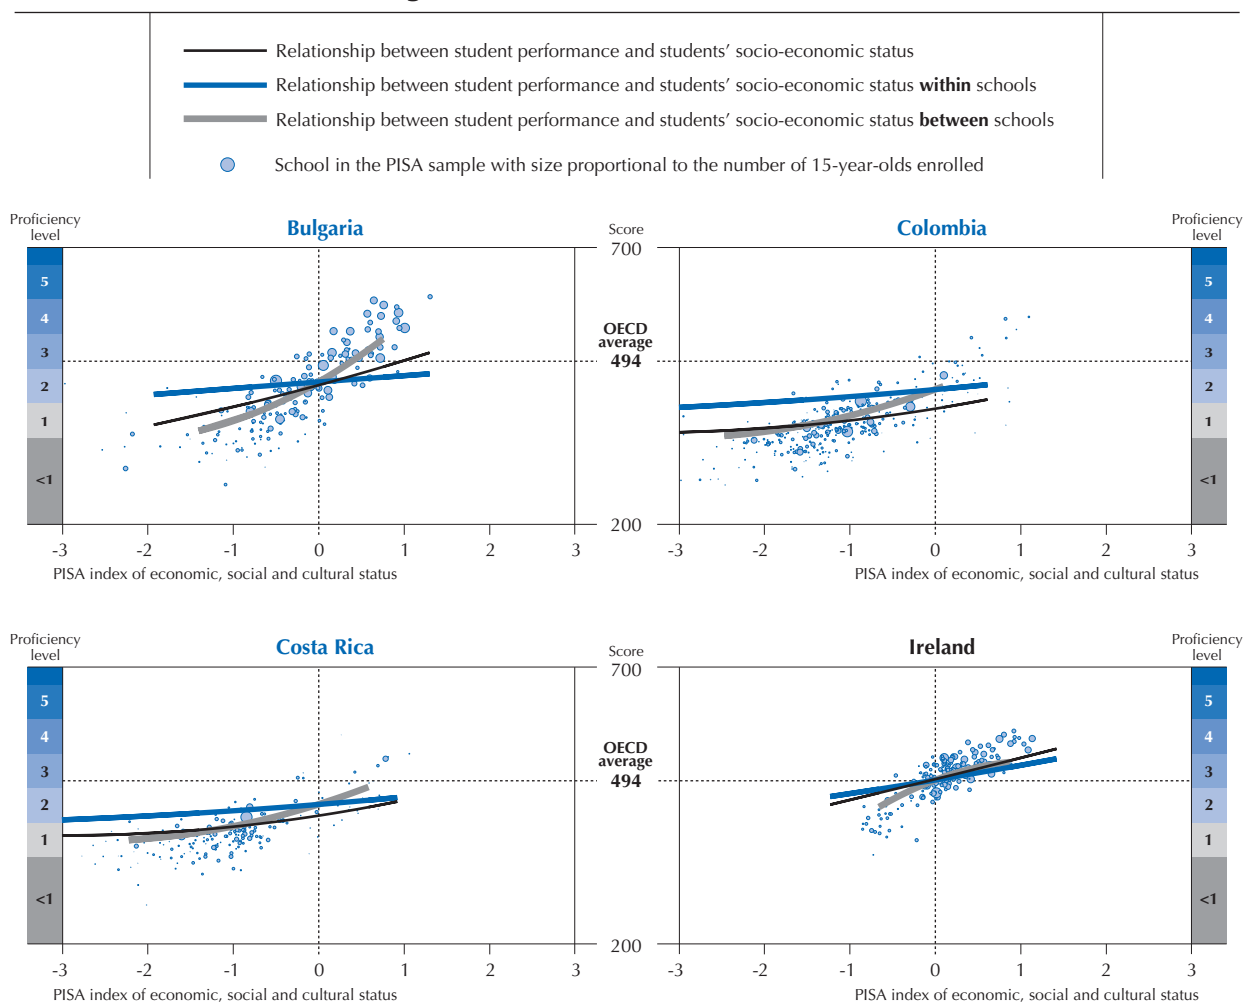

It is equally important to understand the degree of socio-economic disparity within a country when interpreting the relationship between performance and socio-economic status. For example, Bulgaria, Japan, Korea, Luxembourg, Sweden and Uruguay have socio-economic gradients with similar slopes (a performance difference of between 36 and 42 score points related to socio-economic status); but the range of values on the *PISA index of economic, social and cultural status* (the length of the gradient) between the 5th and 95th percentile of students spans at least 3.2 units on the index (more than three times the average difference in socio-economic status between two students randomly chosen across OECD countries) in Bulgaria, Luxembourg and Uruguay, but less than 2.5 units in Japan, Korea and Sweden.

In other words, the populations of 15-year-old students in Bulgaria, Luxembourg and Uruguay are far more socio-economically diverse than the student populations in Japan, Korea and Sweden. This difference partly explains why, in Sweden, for example, socio-economic status accounts for less-than-average variation in performance, while in Uruguay socio-economic status has a stronger-than-average impact on performance. Socio-economic diversity, measured in this way, is greatest in Chile, Mexico, Portugal and Turkey, among OECD countries; but many partner countries and economies also show greater-than-OECD-average socio-economic diversity, particularly Brazil, Colombia, Costa Rica, Peru, Thailand, Tunisia, Uruguay and Viet Nam. In all of these countries and economies, compensatory policies that target disadvantaged students and schools can help improve performance and equity in education.

■ Figure II.5.8 ■

Bulgaria, Colombia, Costa Rica and Ireland**

Source: OECD, PISA 2012 Database.

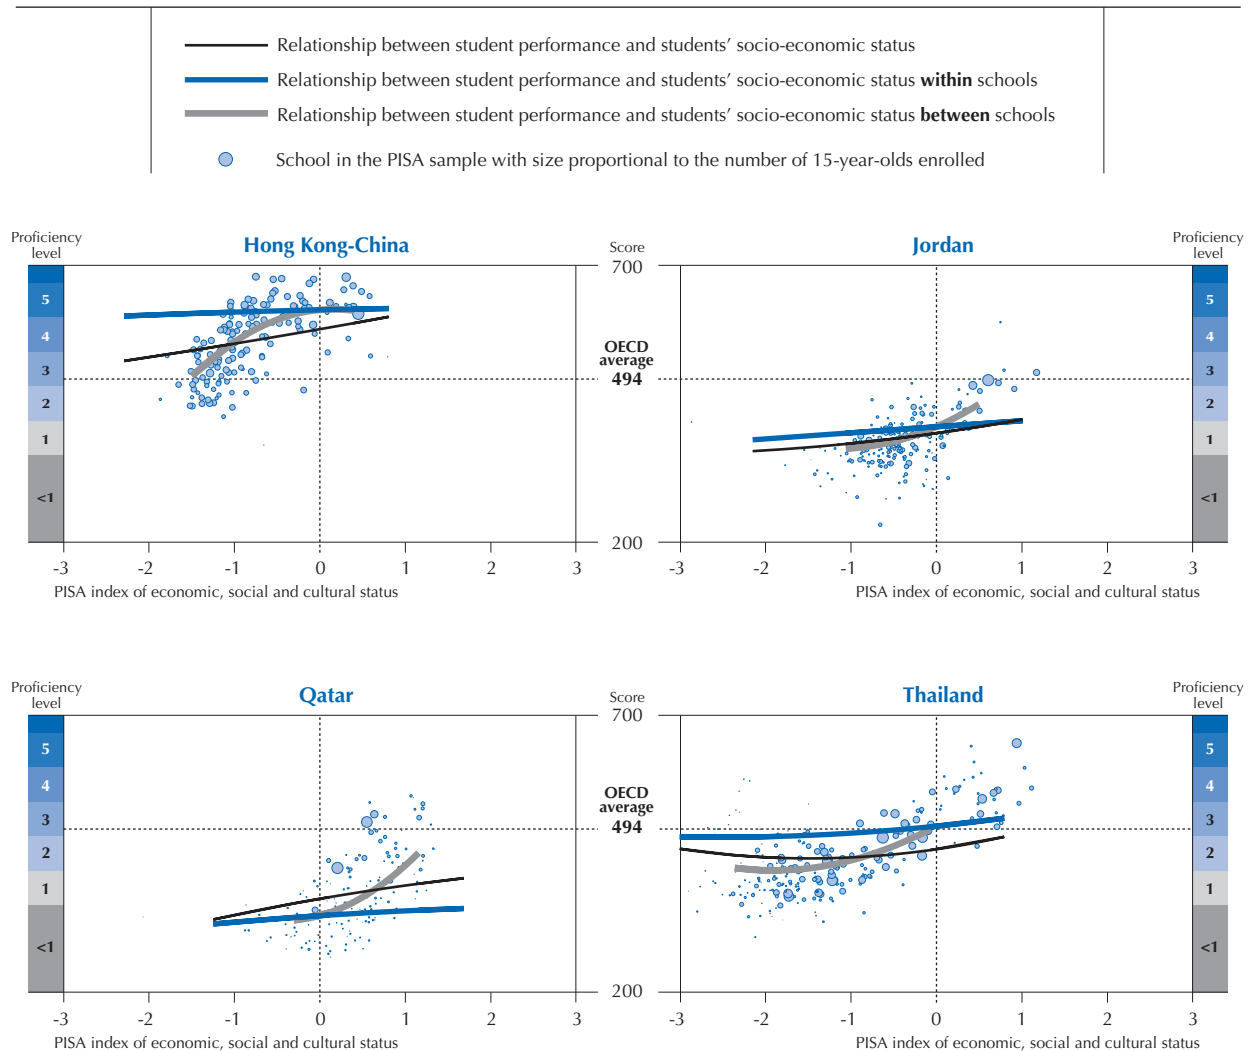

StatLink <http://dx.doi.org/10.1787/888932965098>

In countries with large disparities and a weak relationship between socio-economic status and performance, such as Mexico and Thailand, compensatory policies to help the most disadvantaged students would be effective. By contrast, where socio-economic disparities are smaller and have a weaker effect on performance, for example in the Czech Republic, Finland, Japan, Korea and Norway, policies targeting social reform are unlikely to be the most effective way of improving student performance because they are not likely to reach many students.

■ Figure II.5.9 ■

StatLink  <http://dx.doi.org/10.1787/888932965117>

TARGETING LOW-PERFORMING AND SOCIO-ECONOMICALLY DISADVANTAGED SCHOOLS

When performance or socio-economic disparities between schools are large, policies that target schools rather than students may be more effective, particularly when there is a strong and marked relationship between a school's socio-economic profile and average performance.

The relationship between a school's socio-economic profile and student performance can be described in several ways. One way is to focus on how much better a student who goes to a school with a more advantaged student population can be expected to perform in mathematics. A second is how closely the performance of individual students actually follows this prediction, or the strength of the relationship.¹ These factors are all important in countries where students' opportunities to learn are strongly affected by differences in schools' socio-economic profile. In countries where large differences are observed, policies that target disadvantaged schools are more likely to succeed in improving performance and equity.

As Figure II.5.1b shows, in Uruguay, 74% of the difference in student performance across schools is related to socio-economic factors, that is, schools tend to fall into two categories: higher-performing schools with a more advantaged socio-economic profile, and schools with lower performance and more disadvantaged student populations. Most important, the variation in the socio-economic profile of schools is great, meaning that there is a large difference in socio-economic status between advantaged and disadvantaged schools. In Iceland, while performance disparities related to schools' socio-economic profile are comparatively large as well (69%), the overall differences in the socio-economic profiles of schools are much smaller. That explains why Iceland has, overall, one of the more equitable education systems while Uruguay has one of the least equitable systems. In countries in which most of the variation is accounted for by between-school socio-economic factors, policies aimed at reducing social segregation should be a priority, as such disparities among schools tend to reinforce the inequities of the system.

■ Figure II.5.10 ■

Relationship between school performance and schools' socio-economic profiles in countries with strong between-school gradients: Iceland and Uruguay

Source: OECD, PISA 2012 Database.

StatLink  <http://dx.doi.org/10.1787/888932965136>

A similar contrast can be observed among countries where performance differences across socio-economic status are relatively small. For example, in Norway and Portugal, the between-school differences in mathematics performance are relatively small, around 49 and 33 score points, respectively (compared to an OECD average of more than 70 score points). However, schools vary considerably in their socio-economic profile. A school's socio-economic profile is a much better predictor of performance in Portugal, where 62% of the variation in performance is explained by the schools' socio-economic profile, than in Norway, where 46% of the variation in performance is so explained. That is, while many schools in Norway perform differently than what would have been predicted based on their socio-economic profile, in Portugal, socio-economic status is closely associated with a school's performance. Policies that target disadvantaged schools are thus more likely to be effective in Portugal. In Norway, these policies will not help low-performing schools that are not necessarily disadvantaged.

Targeting disadvantaged schools may be a viable option in those countries where differences in socio-economic profiles are large (i.e. the between-school socio-economic differences account for a large proportion of the variation in socio-economic status). Such policies may prove particularly effective where the relationship between performance and socio-economic status at the school level is marked, either because there are large performance differences across schools with different socio-economic profiles or because there is a strong relationship between the socio-economic profile of a school and mean student performance at the school.

■ Figure II.5.11 ■

Relationship between school performance and schools' socio-economic profile in countries with weak between-school gradients: Norway and Portugal

Source: OECD, PISA 2012 Database.

StatLink <http://dx.doi.org/10.1787/888932965155>

Targeting disadvantaged schools may be important in Hungary, Shanghai-China and the Slovak Republic, where socio-economic differences between schools are large – they account for a larger-than-average proportion of the variation in socio-economic status (37%, 33% and 36%, respectively, compared with the OECD average of 24%, [Figure II.5.1b] – and where between-school performance differences across socio-economic groups (98 score points, 88 points and 86 points, respectively) are above the OECD average (72 score points). In all three countries, schools' socio-economic profiles are strongly related to school mean performance, explaining between 65% of the variation in mean school performance in Shanghai-China and 78% in Hungary (compared with an OECD average of 63%). Argentina, Brazil, Bulgaria, Chile, Colombia, Costa Rica, Peru, Portugal, Romania and Uruguay also show large between-school differences in socio-economic profiles and a strong relationship between performance and socio-economic status. In all of these countries, performance differences across schools related to the schools' socio-economic profiles are below average (except in Bulgaria, where they are average); but the strength of the relationship between schools' mean performance and their socio-economic profiles are at or above average. The proportion of the performance differences explained by the variation in socio-economic profiles ranges from 60% in Colombia to 78% in Peru. Hong Kong-China is the only economy where differences between schools in socio-economic profiles are at the OECD average, but the strength of the relationship between schools' socio-economic profiles and performance is below average.

Targeting low-performing schools may also be an option, particularly when the school's socio-economic status is strongly related to performance differences. The evidence in PISA suggests that policies targeting low-performing schools may be particularly effective for Belgium, the Czech Republic, Germany, Hungary, the Slovak Republic and Slovenia. In all of these countries, between-school differences account for at least half of the variation in performance. The school systems of these countries tend to track students into different schools according to their performance, so it is not surprising that there are many between-school performance differences across these countries. The average impact of schools' socio-economic profile on performance (the between-school socio-economic gradient) ranges from 86 score points in the Slovak Republic to 127 points in the Czech Republic, compared with the OECD average difference of 72 score points. In all these countries, more than 70% of the differences in performance are explained by students' and schools' socio-economic status, compared with the OECD average of 63% (Figure II.5.1b). Socio-economic disparities across schools account for more than 35% of the variation in socio-economic status in Hungary and the Slovak Republic. Within-school differences in performance across socio-economic groups are above average only in the Slovak Republic.

TARGETING STUDENTS WITHIN SCHOOLS

To some extent, school systems that separate students into different schools, based on ability, can expect to have narrower differences in student performance within each school, both overall and relative to socio-economic status. The other side of the coin is that the social disparities between schools account for more of the performance differences among these countries than social disparities within schools. Thus, even Korea, one of the most unequal countries in terms of between-school gradients, and Viet Nam, one of the most equal, show similar results when analysed according to within-school gradients (Figure II.5.12). In no country do within-school social differences account for more than 11% of variation in student performance.

In Denmark, Finland, New Zealand, Poland, Portugal, Spain and Sweden, 9% or more of the performance differences within schools are explained by differences in socio-economic status – a stronger-than-average relationship between performance and socio-economic status within schools. In all these countries, school-level policies, in addition to system-level policies, would prove more effective.

Figure II.5.13 shows the relationship between school performance and schools' socio-economic profile for all OECD countries and partner countries and economies that are not used as examples in previous chapters.

Note

1. Note that these results also depend on how schools are defined and organised within countries/economies and by the units that were chosen for sampling purposes. For example, in some countries, some of the schools in the PISA sample were defined as administrative units (even if they spanned several geographically separate institutions, as in Italy; in others, they were defined as those parts of larger educational institutions that serve 15-year-olds; in still others, they were defined as physical school buildings; and in others they were defined from a management perspective (e.g. entities having a principal). The *PISA 2012 Technical Report* (OECD, forthcoming) provides an overview of how schools were defined. Because of the manner in which students were sampled, the within-school variation includes variation between classes as well as between students. In Slovenia, the primary sampling unit is defined as a group of students who follow the same study programme within a school (an educational track within a school). So in this particular case, the between-school variance is actually the difference between tracks within the schools.

Notes regarding Cyprus

Note by Turkey: The information in this document with reference to “Cyprus” relates to the southern part of the Island. There is no single authority representing both Turkish and Greek Cypriot people on the Island. Turkey recognises the Turkish Republic of Northern Cyprus (TRNC). Until a lasting and equitable solution is found within the context of the United Nations, Turkey shall preserve its position concerning the “Cyprus issue”.

Note by all the European Union Member States of the OECD and the European Union: The Republic of Cyprus is recognised by all members of the United Nations with the exception of Turkey. The information in this document relates to the area under the effective control of the Government of the Republic of Cyprus.

A note regarding Israel

The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law.

ANNEX A1

CONSTRUCTION OF MATHEMATICS SCALES AND INDICES FROM THE STUDENT, SCHOOL AND PARENT CONTEXT QUESTIONNAIRES

How the PISA 2012 mathematics assessments were designed, analysed and scaled

The development of the PISA 2012 mathematics tasks was co-ordinated by an international consortium of educational research institutions contracted by the OECD, under the guidance of a group of mathematics experts from participating countries. Participating countries contributed stimulus material and questions, which were reviewed, tried out and refined iteratively over the three years leading up to the administration of the assessment in 2012. The development process involved provisions for several rounds of commentary from participating countries and economies, as well as small-scale piloting and a formal field trial in which samples of 15-year-olds (about 1 000 students) from participating countries and economies took part. The mathematics expert group recommended the final selection of tasks, which included material submitted by participating countries and economies. The selection was made with regard to both their technical quality, assessed on the basis of their performance in the field trial, and their cultural appropriateness and interest level for 15-year-olds, as judged by the participating countries. Another essential criterion for selecting the set of material as a whole was its fit to the framework described in Volume 1, in order to maintain the balance across various categories of context, content and process. Finally, it was carefully ensured that the set of questions covered a range of difficulty, allowing good measurement and description of the mathematics literacy of all 15-year-old students, from the least proficient to the highly able.

More than 110 print mathematics questions were used in PISA 2012, but each student in the sample only saw a fraction of the total pool because different sets of questions were given to different students. The mathematics questions selected for inclusion in PISA 2012 were organised into half-hour clusters. These, along with clusters of reading and science questions, were assembled into booklets containing four clusters each. Each participating student was then given a two-hour assessment. As mathematics was the focus of the PISA 2012 assessment, every booklet included at least one cluster of mathematics material. The clusters were rotated so that each cluster appeared in each of the four possible positions in the booklets, and each pair of clusters appeared in at least one of the 13 booklets that were used.

This design, similar to those used in previous PISA assessments, makes it possible to construct a single scale of mathematics proficiency, in which each question is associated with a particular point on the scale that indicates its difficulty, whereby each student's performance is associated with a particular point on the same scale that indicates his or her estimated proficiency. A description of the modelling technique used to construct this scale can be found in the *PISA 2012 Technical Report* (OECD, forthcoming).

The relative difficulty of tasks in a test is estimated by considering the proportion of test takers who answer each question correctly. The relative proficiency of students taking a particular test can be estimated by considering the proportion of test questions they answer correctly. A single continuous scale shows the relationship between the difficulty of questions and the proficiency of students. By constructing a scale that shows the difficulty of each question, it is possible to locate the level of mathematics literacy that the question represents. By showing the proficiency of each student on the same scale, it is possible to describe the level of mathematics literacy that the student possesses.

The location of student proficiency on this scale is set in relation to the particular group of questions used in the assessment. However, just as the sample of students taking PISA in 2012 is drawn to represent all the 15-year-olds in the participating countries and economies, so the individual questions used in the assessment are designed to represent the definition of mathematics literacy adequately. Estimates of student proficiency reflect the kinds of tasks they would be expected to perform successfully. This means that students are likely to be able to complete questions successfully at or below the difficulty level associated with their own position on the scale (but they may not always do so). Conversely, they are unlikely to be able to successfully complete questions above the difficulty level associated with their position on the scale (but they may sometimes do so).

The further a student's proficiency is located above a given question, the more likely he or she is to successfully complete the question (and other questions of similar difficulty); the further the student's proficiency is located below a given question, the lower the probability that the student will be able to successfully complete the question, and other questions of similar difficulty.

How mathematics proficiency levels are defined in PISA 2012

PISA 2012 provides an overall mathematics literacy scale, drawing on all the questions in the mathematics assessment, as well as scales for three process and four content categories. The metric for the overall mathematics scale is based on a mean for OECD countries set at 500 in PISA 2003, with a standard deviation of 100. To help interpret what students' scores mean in substantive terms, the scale is divided into levels, based on a set of statistical principles, and then descriptions are generated, based on the tasks that are located within each level, to describe the kinds of skills and knowledge needed to successfully complete those tasks.

For PISA 2012, the range of difficulty of tasks allows for the description of six levels of mathematics proficiency: Level 1 is the lowest described level, then Level 2, Level 3 and so on up to Level 6.

Students with a proficiency within the range of Level 1 are likely to be able to successfully complete Level 1 tasks (and others like them), but are unlikely to be able to complete tasks at higher levels. Level 6 reflects tasks that present the greatest challenge in terms

of mathematics skills and knowledge. Students with scores in this range are likely to be able to complete mathematics tasks located at that level successfully, as well as all the other mathematics tasks in PISA.

PISA applies a standard methodology for constructing proficiency scales. Based on a student's performance on the tasks in the test, his or her score is generated and located in a specific part of the scale, thus allowing the score to be associated with a defined proficiency level. The level at which the student's score is located is the highest level for which he or she would be expected to answer correctly most of a random selection of questions within the same level. Thus, for example, in an assessment composed of tasks spread uniformly across Level 3, students with a score located within Level 3 would be expected to complete at least 50% of the tasks successfully. Because a level covers a range of difficulty and proficiency, success rates across the band vary. Students near the bottom of the level would be likely to succeed on just over 50% of the tasks spread uniformly across the level, while students at the top of the level would be likely to succeed on well over 70% of the same tasks.

Figure I.2.21 in Volume I provides details of the nature of mathematics skills, knowledge and understanding required at each level of the mathematics scale.

Context questionnaire indices

This section explains the indices derived from the student and school context questionnaires used in PISA 2012.

Several PISA measures reflect indices that summarise responses from students, their parents or school representatives (typically principals) to a series of related questions. The questions were selected from a larger pool of questions on the basis of theoretical considerations and previous research. The *PISA 2012 Assessment and Analytical Framework* (OECD, 2013) provides an in-depth description of this conceptual framework. Structural equation modelling was used to confirm the theoretically expected behaviour of the indices and to validate their comparability across countries and economies. For this purpose, a model was estimated separately for each country and collectively for all OECD countries. For a detailed description of other PISA indices and details on the methods, see *PISA 2012 Technical Report* (OECD, forthcoming).

There are two types of indices: simple indices and scale indices.

Simple indices are the variables that are constructed through the arithmetic transformation or recoding of one or more items, in exactly the same way across assessments. Here, item responses are used to calculate meaningful variables, such as the recoding of the four-digit ISCO-08 codes into "Highest parents' socio-economic index (HISEI)" or, teacher-student ratio based on information from the school questionnaire.

Scale indices are the variables constructed through the scaling of multiple items. Unless otherwise indicated, the index was scaled using a weighted likelihood estimate (WLE) (Warm, 1989), using a one-parameter item response model (a partial credit model was used in the case of items with more than two categories). For details on how each scale index was constructed see the *PISA 2012 Technical Report* (OECD, forthcoming). In general, the scaling was done in three stages:

- The item parameters were estimated from equal-sized subsamples of students from all participating countries and economies.
- The estimates were computed for all students and all schools by anchoring the item parameters obtained in the preceding step.
- The indices were then standardised so that the mean of the index value for the OECD student population was zero and the standard deviation was one (countries being given equal weight in the standardisation process).

Sequential codes were assigned to the different response categories of the questions in the sequence in which the latter appeared in the student, school or parent questionnaires. Where indicated in this section, these codes were inverted for the purpose of constructing indices or scales. Negative values for an index do not necessarily imply that students responded negatively to the underlying questions. A negative value merely indicates that the respondents answered less positively than all respondents did on average across OECD countries. Likewise, a positive value on an index indicates that the respondents answered more favourably, or more positively, than respondents did, on average, across OECD countries. Terms enclosed in brackets < > in the following descriptions were replaced in the national versions of the student, school and parent questionnaires by the appropriate national equivalent. For example, the term <qualification at ISCED level 5A> was translated in the United States into "Bachelor's degree, post-graduate certificate program, Master's degree program or first professional degree program". Similarly the term <classes in the language of assessment> in Luxembourg was translated into "German classes" or "French classes" depending on whether students received the German or French version of the assessment instruments.

In addition to simple and scaled indices described in this annex, there are a number of variables from the questionnaires that correspond to single items not used to construct indices. These non-recoded variables have prefix of "ST" for the questionnaire items in the student questionnaire, "SC" for the items in the school questionnaire, and "PA" for the items in the parent questionnaire. All the context questionnaires as well as the PISA international database, including all variables, are available through www.pisa.oecd.org.

Scaling of questionnaire indices for trend analyses

In PISA, to gather information about students' and schools' characteristics, both students and schools complete a background questionnaire. In PISA 2003 and PISA 2012 several questions were kept untouched, enabling the comparison of responses to these

questions over time. In this report, only questions that maintained an exact wording are used for trends analyses. Questions with subtle word changes or questions with major word changes were not compared across time because it is impossible to discern whether observed changes in the response are due to changes in the construct they are measuring or to changes in the way the construct is being measured.

Also, in PISA, as described in this Annex, questionnaire items are used to construct indices. Whenever the questions used in the construction of indices remains intact in PISA 2003 and PISA 2012, the corresponding indices are compared. Two types of indices are used in PISA: simple indices and scale indices.

Simple indices recode a set of responses to questionnaire items. For trends analyses, the values observed in PISA 2003 are compared directly to PISA 2012, just as simple responses to questionnaire items are. This is the case of indices like student-teacher ratio and ability grouping in mathematics.

Scale indices, on the other hand, imply WLE estimates which require rescaling in order to be comparable across PISA cycles. Scale indices, like the *PISA index of economic, social and cultural status*, the *index of sense of belonging*, the *index of attitudes towards school*, the *index of intrinsic motivation to learn mathematics*, the *index of instrumental motivation to learn mathematics*, the *index of mathematics self-efficacy*, the *index of mathematics self-concept*, the *index of anxiety towards mathematics*, the *index of teacher shortage*, the *index of quality of physical infrastructure*, the *index of quality of educational resources*, the *index of disciplinary climate*, the *index of teacher-student relations*, the *index of teacher morale*, the *index of student-related factors affecting school climate* and the *index of teacher-related factors affecting school climate*, were scaled, in PISA 2012 to have an OECD average of 0 and a standard deviation of 1, on average, across OECD countries. These same scales were scaled, in PISA 2003, to have an OECD average of 0 and a standard deviation of 1. Because they are on different scales, values reported in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) cannot be compared with those reported in this volume. To make these scale indices comparable, values for 2003 have been rescaled to the 2012 scale, using the PISA 2012 parameter estimates.

These re-scaled indices are available at www.pisa.oecd.org. They can be merged to the corresponding PISA 2003 dataset using the country names, school and student-level identifiers. The rescaled *PISA index of economic, social and cultural status* is also available to be merged with the PISA 2000, PISA 2006 and PISA 2009 dataset.

Student-level simple indices

Age

The variable AGE is calculated as the difference between the middle month and the year in which students were assessed and their month and year of birth, expressed in years and months.

Study programme

In PISA 2012, study programmes available to 15-year-old students in each country were collected both through the student tracking form and the student questionnaire (ST02). All study programmes were classified using ISCED (OECD, 1999). In the PISA international database, all national programmes are indicated in a variable (PROGN) where the first six digits refer to the national centre code and the last two digits to the national study programme code.

The following internationally comparable indices were derived from the data on study programmes:

- Programme level (ISCEDL) indicates whether students are (1) primary education level (ISCED 1); (2) lower-secondary education level; or (3) upper secondary education level.
- Programme designation (ISCEDD) indicates the designation of the study programme: (1) "A" (general programmes designed to give access to the next programme level); (2) "B" (programmes designed to give access to vocational studies at the next programme level); (3) "C" (programmes designed to give direct access to the labour market); or (4) "M" (modular programmes that combine any or all of these characteristics).
- Programme orientation (ISCEDO) indicates whether the programme's curricular content is (1) general; (2) pre-vocational; (3) vocational; or (4) modular programmes that combine any or all of these characteristics.

Occupational status of parents

Occupational data for both a student's father and a student's mother were obtained by asking open-ended questions in the student questionnaire (ST12, ST16). The responses were coded to four-digit ISCO codes (ILO, 1990) and then mapped to the SEI index of Ganzeboom et al. (1992). Higher scores of SEI indicate higher levels of occupational status. The following three indices are obtained:

- Mother's occupational status (OCOD1).
- Father's occupational status (OCOD2).
- The highest occupational level of parents (HISEI) corresponds to the higher SEI score of either parent or to the only available parent's SEI score.

[Part 1/1]

Table A1.1 Levels of parental education converted into years of schooling

		Completed ISCED level 1 (primary education)	Completed ISCED level 2 (lower secondary education)	Completed ISCED levels 3B or 3C (upper secondary education providing direct access to the labour market or to ISCED 5B programmes)	Completed ISCED level 3A (upper secondary education providing access to ISCED 5A and 5B programmes) and/ or ISCED level 4 (non- tertiary post-secondary)	Completed ISCED level 5A (university level tertiary education) or ISCED level 6 (advanced research programmes)	Completed ISCED level 5B (non-university tertiary education)

1. In Belgium the distinction between universities and other tertiary schools doesn't match the distinction between ISCED 5A and ISCED 5B.

2. In the Slovak Republic, university education (ISCED 5A) usually lasts five years and doctoral studies (ISCED 6) lasts three more years. Therefore, university graduates will have completed 18 years of study and graduates of doctoral programmes will have completed 21 years of study.

Some of the analyses distinguish between four different categories of occupations by the major groups identified by the ISCO coding of the highest parental occupation: Elementary (ISCO 9), semi-skilled blue-collar (ISCO 6, 7 and 8), semi-skilled white-collar (ISCO 4 and 5), skilled (ISCO 1, 2 and 3). This classification follows the same methodology used in other OECD publications such as *Education at a Glance* (2013b) and the *OECD Skills Outlook* (2013c).¹

Educational level of parents

The educational level of parents is classified using ISCED (OECD, 1999) based on students' responses in the student questionnaire (ST13, ST14, ST17 and ST18).

As in PISA 2000, 2003, 2006 and 2009, indices were constructed by selecting the highest level for each parent and then assigning them to the following categories: (0) None, (1) ISCED 1 (primary education), (2) ISCED 2 (lower secondary), (3) ISCED level 3B or 3C (vocational/pre-vocational upper secondary), (4) ISCED 3A (upper secondary) and/or ISCED 4 (non-tertiary post-secondary), (5) ISCED 5B (vocational tertiary), (6) ISCED 5A, 6 (theoretically oriented tertiary and post-graduate). The following three indices with these categories are developed:

- Mother's educational level (MISCED).
- Father's educational level (FISCED).
- Highest educational level of parents (HISCED) corresponds to the higher ISCED level of either parent.

Highest educational level of parents was also converted into the number of years of schooling (PARED). For the conversion of level of education into years of schooling, see Table A1.1.

Immigration and language background

Information on the country of birth of students and their parents is collected in a similar manner as in PISA 2000, PISA 2003, PISA 2006 and PISA 2009 by using nationally specific ISO coded variables. The ISO codes of the country of birth for students and their parents are available in the PISA international database (COBN_S, COBN_M, and COBN_F).

The index on immigrant background (IMMIG) has the following categories: (1) non-immigrant students (those students born in the country of assessment, or those with at least one parent born in that country; students who were born abroad with at least one parent born in the country of assessment are also classified as non-immigrant students), (2) second-generation students (those born in the country of assessment but whose parents were born in another country) and (3) first-generation students (those born outside the country of assessment and whose parents were also born in another country). Students with missing responses for either the student or for both parents, or for all three questions have been given missing values for this variable.

Students indicate the language they usually speak at home. The data are captured in nationally-specific language codes, which were recoded into variable LANGN with the following two values: (1) language at home is the same as the language of assessment, and (2) language at home is a different language than the language of assessment.

Relative grade

Data on the student's grade are obtained both from the student questionnaire (ST01) and from the student tracking form. As with all variables that are on both the tracking form and the questionnaire, inconsistencies between the two sources are reviewed and resolved during data-cleaning. In order to capture between-country variation, the relative grade index (GRADE) indicates whether students are at the modal grade in a country (value of 0), or whether they are below or above the modal grade level (+ x grades, - x grades).

The relationship between the grade and student performance was estimated through a multilevel model accounting for the following background variables: *i*) the *PISA index of economic, social and cultural status*; *ii*) the *PISA index of economic, social and cultural status squared*; *iii*) the school mean of the *PISA index of economic, social and cultural status*; *iv*) an indicator as to whether students were foreign-born first-generation students; *v*) the percentage of first-generation students in the school; and *vi*) students' gender.

Table A1.2 presents the results of the multilevel model. Column 1 in Table A1.2 estimates the score-point difference that is associated with one grade level (or school year). This difference can be estimated for the 32 OECD countries in which a sizeable number of 15-year-olds in the PISA samples were enrolled in at least two different grades. Since 15-year-olds cannot be assumed to be distributed at random across the grade levels, adjustments had to be made for the above-mentioned contextual factors that may relate to the assignment of students to the different grade levels. These adjustments are documented in columns 2 to 7 of the table. While it is possible to estimate the typical performance difference among students in two adjacent grades net of the effects of selection and contextual factors, this difference cannot automatically be equated with the progress that students have made over the last school year but should be interpreted as a lower boundary of the progress achieved. This is not only because different students were assessed but also because the content of the PISA assessment was not expressly designed to match what students had learned in the preceding school year but more broadly to assess the cumulative outcome of learning in school up to age 15. For example, if the curriculum of the grades in which 15-year-olds are enrolled mainly includes material other than that assessed by PISA (which, in turn, may have been included in earlier school years) then the observed performance difference will underestimate student progress.

[Part 1/1]

Table A1.2 A multilevel model to estimate grade effects in mathematics accounting for some background variables

Note: Values that are statistically significant are indicated in bold (see Annex A3).

1. Multilevel regression model (student and school levels): Mathematics performance is regressed on the variables of school policies and practices presented in this table.

* See notes at the beginning of this Annex.

StatLink  <http://dx.doi.org/10.1787/888932937073>

Learning time

Learning time in test language (LMINS) was computed by multiplying students' responses on the number of minutes on average in the test language class by number of test language class periods per week (ST69 and ST70). Comparable indices were computed for mathematics (MMINS) and science (SMINS).

Student-level scale indices

Instrumental motivation to learn mathematics

The *index of instrumental motivation to learn mathematics* (INSTMOT) was constructed using student responses over the extent they strongly agreed, agreed, disagreed or strongly disagreed to a series of statements in question (ST29) when asked to think about their views on mathematics: Making an effort in mathematics is worth because it will help me in the work that I want to do later on; Learning mathematics is worthwhile for me because it will improve my career <prospects, chances>; Mathematics is an important subject for me because I need it for what I want to study later on; I will learn many things in mathematics that will help me get a job. See Annex A6 for the description of adjusted indices.

For trends analyses, the PISA 2003 values of the index of instrumental motivation to learn mathematics were rescaled to be comparable to those in PISA 2012. As a result, values for the index of instrumental motivation to learn mathematics for PISA 2003 reported in this volume may differ from those reported in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004).

Disciplinary climate

The *index of disciplinary climate* (DISCLIMA) was derived from students' reports on how often the followings happened in their lessons of the language of instruction (ST81): *i*) students don't listen to what the teacher says; *ii*) there is noise and disorder; *iii*) the teacher has to wait a long time for the students to <quieten down>; *iv*) students cannot work well; and *v*) students don't start working for a long time after the lesson begins. In this index higher values indicate a better disciplinary climate.

For trends analyses, the PISA 2003 values of the index of disciplinary climate were rescaled to be comparable to those in PISA 2012. As a result, values for the index of disciplinary climate for PISA 2003 reported in this volume may differ from those reported in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004).

Teacher-student relations

The *index of teacher-student relations* (STUDREL) was derived from students' level of agreement with the following statements. The question asked (ST86) stated "Thinking about the teachers at your school: to what extent do you agree with the following statements": *i*) Students get along well with most of my teachers; *ii*) Most teachers are interested in students' well-being; *iii*) Most of my teachers really listen to what I have to say; *iv*) if I need extra help, I will receive it from my teachers; and *v*) Most of my teachers treat me fairly. Higher values on this index indicate positive teacher-student relations.

For trends analyses, the PISA 2003 values of the index of student-teacher relations were rescaled to be comparable to those in PISA 2012. As a result, values for the index of student-teacher relations for PISA 2003 reported in this volume may differ from those reported in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004).

Economic, social and cultural status

The *PISA index of economic, social and cultural status* (ESCS) was derived from the following three indices: *highest occupational status of parents* (HISEI), *highest educational level of parents* in years of education according to ISCED (PARED), and *home possessions* (HOMEPOS). The *index of home possessions* (HOMEPOS) comprises all items on the indices of WEALTH, CULTPOSS and HEDRES, as well as books in the home recoded into a four-level categorical variable (0-10 books, 11-25 or 26-100 books, 101-200 or 201-500 books, more than 500 books).

The *PISA index of economic, social and cultural status* (ESCS) was derived from a principal component analysis of standardised variables (each variable has an OECD mean of zero and a standard deviation of one), taking the factor scores for the first principal component as measures of the *PISA index of economic, social and cultural status*.

Principal component analysis was also performed for each participating country or economy to determine to what extent the components of the index operate in similar ways across countries or economy. The analysis revealed that patterns of factor loading were very similar across countries, with all three components contributing to a similar extent to the index (for details on reliability and factor loadings, see the *PISA 2012 Technical Report* (OECD, forthcoming).

The imputation of components for students with missing data on one component was done on the basis of a regression on the other two variables, with an additional random error component. The final values on the *PISA index of economic, social and cultural status* (ESCS) for 2012 have an OECD mean of 0 and a standard deviation of one.

ESCS was computed for all students in the five cycles, and ESCS indices for trends analyses were obtained by applying the parameters used to derive standardised values in 2012 to the ESCS components for previous cycles. These values will therefore not be directly comparable to ESCS values in the databases for previous cycles, though the differences are not large for the 2006 and 2009 cycles. ESCS values in earlier cycles were computed using different algorithms, so for 2000 and 2003 the differences are larger.

Changes to the computation of socio-economic status for PISA 2012

While the computation of socio-economic status followed what had been done in previous cycles, PISA 2012 undertook an important upgrade with respect to the coding of parental occupation. Prior to PISA 2012, the 1988 International Standard Classification of Occupations (ISCO-88) was used for the coding of parental occupation. By 2012, however, ISCO-88 was almost 25 years old and it was no longer tenable to maintain its use as an occupational coding scheme.² It was therefore decided to use its replacement, ISCO-08, for occupational coding in PISA 2012.

The change from ISCO-88 to ISCO-08 required an update of the International Socio-Economic Index (ISEI) of occupation codes. PISA 2012 therefore used a modified quantification scheme for ISCO-08 (referred to as ISEI-08), as developed by Harry Ganzeboom (2010). ISEI-08 was constructed using a database of 198 500 men and women with valid education, occupation and (personal) incomes derived from the combined 2002-07 datasets of the International Social Survey Programme (ISSP) (Ganzeboom, 2010). The methodology used for this purpose was similar to the one employed in the construction of ISEI for ISCO-68 and ISCO-88 described in different publications (Ganzeboom, de Graff and Treiman, 1992; Ganzeboom and Treiman, 1996; Ganzeboom and Treiman, 2003).³

The main differences with regard to the previous ISEI construction are the following:

- A new database was used which is more recent, larger and cross-nationally more diverse than the one used earlier.
- The new ISEI was constructed using data for women and men, while previously only men were used to estimate the scale. The data on income were corrected for hours worked to adjust the different prevalence of part-time work between men and women in many countries.

A range of validation activities accompanied the transition from ISCO-88/ISEI-88 to ISCO-08/ISEI-08, including a comparison of *i*) the distributions of ISEI-88 with ISEI-08 in terms of range, mean and standard deviations for both mothers' and fathers' occupations and *ii*) correlations between the two ISEI indicators and performance, again separately undertaken for mothers' and fathers' occupations.

For this cycle, in order to obtain trends for all cycles from 2000 to 2012, the computation of the indices WEALTH, HEDRES, CULTPOSS and HOMEPOS was based on data from all cycles from 2000 to 2012. HOMEPOS is of particular importance as it is used in the computation of ESCS. These were then standardised on 2012 so that the OECD mean is 0 and the standard deviation is 1. This means that the indices calculated on the previous cycle will be on the 2012 scale and thus not directly comparable to the indices in the database for the previously released cycles. To estimate item parameters for scaling, a calibration sample from all cycles was used, consisting of 500 students from all countries in the previous cycles, and 750 from 2012, as any particular student questionnaire item only occurs in two-thirds of the questionnaires in 2012.

The items used in the computation of the indices has changed to some extent from cycle to cycle, though cycles they have remained much the same from 2006 to 2012. The earlier cycles were are in general missing a few items that are present in the later cycles, but it was felt leaving out items only present in the later cycles would give too much weight to the earlier cycles. So a superset of all items (except country specific items) in the five cycles was used, and international item parameters were derived from this set.

The second step was to estimate WLEs for the indices, anchoring parameters on the international item set while estimating the country specific item parameters. This is the same procedure used in previous cycles.

Family wealth

The *index of family wealth* (WEALTH) is based on students' responses on whether they had the following at home: a room of their own, a link to the Internet, a dishwasher (treated as a country-specific item), a DVD player, and three other country-specific items (some items in ST26); and their responses on the number of cellular phones, televisions, computers, cars and the number of rooms with a bath or shower (ST27).

Home educational resources

The *index of home educational resources* (HEDRES) is based on the items measuring the existence of educational resources at home including a desk and a quiet place to study, a computer that students can use for schoolwork, educational software, books to help with students' school work, technical reference books and a dictionary (some items in ST26).

Cultural possessions

The *index of cultural possessions* (CULTPOSS) is based on students' responses to whether they had the following at home: classic literature, books of poetry and works of art (some items in ST26).

The rotated design of the student questionnaire

A major innovation in PISA 2012 is the rotated design of the student questionnaire. One of the main reasons for a rotated design, which had previously been implemented for the cognitive assessment, was to extend the content coverage of the student questionnaire. Table A1.3 provides an overview of the rotation design and content of questionnaire forms for the main survey.

Table A1.3 Student questionnaire rotation design

Form A	Common Question Set (all forms)	Question Set 1 – Mathematics Attitudes/ Problem Solving	Question Set 3 – Opportunity to Learn/ Learning Strategies

Form C	Common Question Set (all forms)	Question Set 3 – Opportunity to Learn/ Learning Strategies	Question Set 2 – School Climate/Attitudes towards School/Anxiety

Note: For details regarding the questions in each question set, please refer to the *PISA 2012 Technical Report* (OECD, forthcoming).

The *PISA 2012 Technical Report* (OECD, forthcoming) provides all details regarding the rotated design of the student questionnaire in PISA 2012, including its implications in terms of *i*) proficiency estimates, *ii*) international reports and trends, *iii*) further analyses, *iv*) structure and documentation of the international database, and *v*) logistics. The rotated design has negligible implications for proficiency estimates and correlations of proficiency estimates with context constructs. The international database (available at www.pisa.oecd.org) includes all background variables for each student. The variables based on the questions that students answered reflect their responses; those that are based on questions that were not administered show a distinctive missing code. Rotation allows the estimation of a full co-variance matrix which means that all variables can be correlated with all other variables. It does not affect conclusions in terms of whether or not an effect would be considered significant in multilevel models.

School-level simple indices

School and class size

The *index of school size* (SCHSIZE) was derived by summing up the number of girls and boys at a school (SC07).

Student-teacher ratio

The *student-teacher ratio* (STRATIO) was obtained by dividing the school size by the total number of teachers (SC09). The number of part-time teachers was weighted by 0.5 and the number of full-time teachers was weighted by 1.0 in the computation of this index.

The *student-mathematics teacher ratio* (SMRATIO) was obtained by dividing the school size by the total number of mathematics teachers (SC10Q11 and SC10Q12). The number of part-time mathematics teachers was weighted by 0.5 and the number of full time mathematics teachers was weighted by 1.0 in the computation of this index.

School type

Schools are classified as either public or private, according to whether a private entity or a public agency has the ultimate power to make decisions concerning its affairs (SC01). This information is combined with SC02 which provides information on the percentage of total funding which comes from government sources to create the *index of school type* (SCHLTYPE). This index has three categories: (1) government-independent private schools controlled by a non-government organisation or with a governing board not selected by a government agency that receive less than 50% of their core funding from government agencies, (2) government-dependent private schools controlled by a non-government organisation or with a governing board not selected by a government agency that receive more than 50% of their core funding from government agencies, and (3) public schools controlled and managed by a public education authority or agency.

Availability of computers

The *index of computer availability* (RATCMP15) was derived from dividing the number of computers available for educational purposes available to students in the modal grade for 15-year-olds (SC11Q02) by the number of students in the modal grade for 15-year-olds (SC11Q01). The wording of the questions asking about computer availability changed between 2006 and 2009. Comparisons involving availability of computers are possible for 2012 data with 2009 data, but not with 2006 or earlier.

The *index of computers connected to the Internet* (COMPWEB) was derived from dividing the number of computers for educational purposes available to students in the modal grade for 15-year-olds that are connected to the web (SC11Q03) by the number of computers for educational purposes available to students in the modal grade for 15-year-olds (SC11Q02).

Quantity of teaching staff at school

The *proportion of fully certified teachers* (PROPCERT) was computed by dividing the number of fully certified teachers (SC09Q21 plus $0.5 \times \text{SC09Q22}$) by the total number of teachers (SC09Q11 plus $0.5 \times \text{SC09Q12}$). The proportion of teachers who have an ISCED 5A qualification (PROPQUAL) was calculated by dividing the number of these kind of teachers (SC09Q31 plus $0.5 \times \text{SC09Q32}$) by the total number of teachers (SC09Q11 plus $0.5 \times \text{SC09Q12}$). The proportion of mathematics teachers (PROPMATH) was computed by dividing the number of mathematics teachers (SC10Q11 plus $0.5 \times \text{SC10Q12}$) by the total number of teachers (SC09Q11 plus $0.5 \times \text{SC09Q12}$).

The proportion of mathematics teachers who have an ISCED 5A qualification (PROPMA5A) was computed by dividing the number of mathematics teachers who have an ISCED 5A qualification (SC10Q21 plus $0.5 \times \text{SC10Q22}$) by the number of mathematics teachers (SC10Q11 plus $0.5 \times \text{SC10Q12}$).

Although both PISA 2003 and PISA 2012 asked school principals about the school's teaching staff, the wording of the questions on the proportion of teachers with an ISCED 5A qualification changed, rendering comparisons impossible.

Academic selectivity

The index of academic selectivity (SCHSEL) was derived from school principals' responses on how frequently consideration was given to the following two factors when students were admitted to the school, based on a scale with response categories "never", "sometimes" and "always" (SC32Q02 and SC32Q03): students' record of academic performance (including placement tests); and recommendation of feeder schools. This index has the following three categories: (1) schools where these two factors are "never" considered for admission, (2) schools considering at least one of these two factors "sometimes" but neither factor "always", and (3) schools where at least one of these two factors is "always" considered for admission.

Although both PISA 2003 and PISA 2012 asked school principals about the school's criteria for admitting students, the wording of the questions changed, rendering comparisons impossible.

Ability grouping

The index of ability grouping in mathematics classes (ABGMATH) was derived from the two items of school principals' reports on whether their school organises mathematics instruction differently for student with different abilities "for all classes", "for some classes", or "not for any classes" (SC15Q01 for mathematics classes study similar content but at different levels and SC15Q02 for different classes study different content or sets of mathematics topics that have different levels of difficulty). This index has the following three categories: (1) no mathematics classes study different levels of difficulty or different content (i.e. "not for any classes" for both SC15Q01 and SC15Q02); (2) some mathematics classes study different levels of difficulty or different content (i.e. "for some classes" for either SC15Q01 or SC15Q02); (3) all mathematics classes study different levels of difficulty or different content (i.e. "for all classes" for either SC15Q01 or SC15Q02).

Extracurricular activities offered by school

The index of mathematics extracurricular activities at school (MACTIV) was derived from school principals' reports on whether their schools offered the following activities to students in the national modal grade for 15-year-olds in the academic year of the PISA assessment (SC16 and SC21 for the last one): *i*) mathematics club, *ii*) mathematics competition, *iii*) club with a focus on computers/Information, Communication Technology, and *iv*) additional mathematics lessons. This index was developed by summing up the number of activities that a school offers. For "additional mathematics lessons" (SC21), it is counted as one when school principals responded "enrichment mathematics only", "remedial mathematics only" or "without differentiation depending on the prior achievement level of the students"; and it is counted as two when school principals responded "both enrichment and remedial mathematics".

The index of creative extracurricular activities at school (CREACTIV) was derived from school principals' reports on whether their schools offered the following activities to students in the national modal grade for 15-year-olds in the academic year of the PISA assessment (SC16): *i*) band, orchestra or choir, *ii*) school play or school musical, and *iii*) art club or art activities. This index was developed by adding up the number of activities that a school offers.

Use of assessment

School principals were asked to report whether students' assessments are used for the following purposes (SC18): *i*) to inform parents about their child's progress; *ii*) to make decisions about students' retention or promotion; *iii*) to group students for instructional purposes; *iv*) to compare the school to district or national performance; *v*) to monitor the school's progress from year to year; *vi*) to make judgements about teachers' effectiveness; *vii*) to identify aspects of instruction or the curriculum that could be improved; and *viii*) to compare the school with other schools. The index of use of assessment (ASSESS) was derived from these eight items by adding up the number of "yes" in principals' responses to these questions.

School responsibility for resource allocation

School principals were asked to report whether "principals", "teachers", "school governing board", "regional or local education authority" or "national education authority" have a considerable responsibility for the following tasks (SC33): *i*) selecting teachers for hire; *ii*) firing teachers; *iii*) establishing teachers' starting salaries; *iv*) determining teachers' salary increases; *v*) formulating the school budget; and *vi*) deciding on budget allocations within the school. The index of school responsibility for resource allocation (RESPRES) was derived from these six items. The ratio of the number of responsibilities that "principals" and/or "teachers" have for these six items to the number of responsibilities that "regional or local education authority" and/or "national education authority" have for these six items was computed. Positive values on this index indicate relatively more responsibility for schools than local, regional or national education authority. This index has an OECD mean of 0 and a standard deviation of 1.

Although both PISA 2003 and PISA 2012 asked school principals about the school's responsibility for resource allocation, the wording of the questions changed, rendering comparisons impossible.

School responsibility for curriculum and assessment

School principals were asked to report whether “principals”, “teachers”, “school governing board”, “regional or local education authority”, or “national education authority” have a considerable responsibility for the following tasks (SC33): *i*) establishing student assessment policies; *ii*) choosing which textbooks are used; *iii*) determining course content; and *iv*) deciding which courses are offered. The *index of the school responsibility for curriculum and assessment* (RESPCUR) was derived from these four items. The ratio of the number of responsibilities that “principals” and/or “teachers” have for these four items to the number of responsibilities that “regional or local education authority” and/or “national education authority” have for these four items was computed. Positive values on this index indicate relatively more responsibility for schools than local, regional or national education authority. This index has an OECD mean of 0 and a standard deviation of 1.

Although both PISA 2003 and PISA 2012 asked school principals about the school’s responsibility for admission and instruction policies, the wording of the questions changed, rendering comparisons impossible.

School-level scale indices

School principals’ leadership

The *index of school management: framing and communicating the school’s goals and curricular development* (LEADCOM) was derived from school principals’ responses about the frequency with which they were involved in the following school affairs in the previous school year (SC34): *i*) use student performance results to develop the school’s educational goals; *ii*) make sure that the professional development activities of teachers are in accordance with the teaching goals of the school; *iii*) ensure that teachers work according to the school’s educational goals; and *iv*) discuss the school’s academic goals with teachers at faculty meetings. The *index of school management: instructional leadership* (LEADINST) was derived from school principals’ responses about the frequency with which they were involved in the following school affairs in the previous school year (SC34): *i*) promote teaching practices based on recent educational research, *ii*) praise teachers whose students are actively participating in learning, and *iii*) draw teachers’ attention to the importance of pupils’ development of critical and social capacities. The index of school management: promoting instructional improvements and professional development (LEADPD) was derived from school principals’ responses about the frequency with which they were involved in the following school affairs in the previous school year (SC34): *i*) take the initiative to discuss matters, when a teacher has problems in his/her classroom; *ii*) pay attention to disruptive behaviour in classrooms; and *iii*) solve a problem together with a teacher, when the teacher brings up a classroom problem. The *index of school management: teacher participation* (LEADTCH) was derived from school principals’ responses about the frequency with which they were involved in the following school affairs in the previous school year (SC34): *i*) provide staff with opportunities to participate in school decision-making; *ii*) engage teachers to help build a school culture of continuous improvement; and *iii*) ask teachers to participate in reviewing management practices. Higher values on these indices indicate greater involvement of school principals in school affairs.

Teacher shortage

The *index of teacher shortage* (TCSHORT) was derived from four items measuring school principals’ perceptions of potential factors hindering instruction at their school (SC14). These factors are a lack of: *i*) qualified science teachers; *ii*) qualified mathematics teachers; *iii*) qualified <test language> teachers; and *iv*) qualified teachers of other subjects. Higher values on this index indicate school principals’ reports of higher teacher shortage at a school.

For trends analyses, the PISA 2003 values of the index of teacher shortage were rescaled to be comparable to those in PISA 2012. As a result, values for the index of teacher shortage for PISA 2003 reported in this volume may differ from those reported in *Learning for Tomorrow’s World: First Results from PISA 2003* (OECD, 2004).

Quality of school’s educational resources

The *index of quality of school educational resources* (SCMATEDU) was derived from six items measuring school principals’ perceptions of potential factors hindering instruction at their school (SC14). These factors are: *i*) shortage or inadequacy of science laboratory equipment; *ii*) shortage or inadequacy of instructional materials; *iii*) shortage or inadequacy of computers for instruction; *iv*) lack or inadequacy of Internet connectivity; *v*) shortage or inadequacy of computer software for instruction; and *vi*) shortage or inadequacy of library materials. As all items were inverted for scaling, higher values on this index indicate better quality of educational resources.

For trends analyses, the PISA 2003 values of the index of quality of educational resources were rescaled to be comparable to those in PISA 2012. As a result, values for the index of quality educational resources for PISA 2003 reported in this volume may differ from those reported in *Learning for Tomorrow’s World: First Results from PISA 2003* (OECD, 2004). One of the questions included to compute the index of quality of educational resources in PISA 2012 (“lack or inadequacy of internet connection”) was not included in the PISA 2003 questionnaire. Estimation of the PISA 2003 index treats this question as missing and, under the assumption that the relationship between the items remains unchanged with the inclusion of the new questions, the PISA 2003 and PISA 2012 values on the index of quality of educational resources are comparable after the rescaling.

Quality of schools' physical infrastructure

The *index of quality of physicals' infrastructure* (SCMATBUI) was derived from three items measuring school principals' perceptions of potential factors hindering instruction at their school (SC14). These factors are: *i*) shortage or inadequacy of school buildings and grounds; *ii*) shortage or inadequacy of heating/cooling and lighting systems; and *iii*) shortage or inadequacy of instructional space (e.g. classrooms). As all items were inverted for scaling, higher values on this index indicate better quality of physical infrastructure.

For trends analyses, the PISA 2003 values of the index of quality of physical infrastructure were rescaled to be comparable to those in PISA 2012. As a result, values for the index of quality of physical infrastructure for PISA 2003 reported in this volume may differ from those reported in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004).

Teacher behaviour

The *index on teacher-related factors affecting school climate* (TEACCLIM) was derived from school principals' reports on the extent to which the learning of students was hindered by the following factors in their schools (SC22): *i*) students not being encouraged to achieve their full potential; *ii*) poor student-teacher relations; *iii*) teachers having to teach students of heterogeneous ability levels within the same class; *iv*) teachers having to teach students of diverse ethnic backgrounds (i.e. language, culture) within the same class; *v*) teachers' low expectations of students; *vi*) teachers not meeting individual students' needs; *vii*) teacher absenteeism; *viii*) staff resisting change; *ix*) teachers being too strict with students; *x*) teachers being late for classes; and *xi*) teachers not being well prepared for classes. As all items were inverted for scaling, higher values on this index indicate a positive teacher behaviour.

For trends analyses, the PISA 2003 values of the index of teacher-related factors affecting school climate were rescaled to be comparable to those in PISA 2012. As a result, values for the index of teacher-related factors affecting school climate for PISA 2003 reported in this volume may differ from those reported in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004). Four of the questions included to compute the index of teacher-related factors affecting school climate in PISA 2012 ("teachers having to teach students of heterogeneous ability levels within the same class," "teachers having to teach students of diverse ethnic backgrounds (i.e. language, culture) within the same class," "teachers being late for classes," and "teachers not being well prepared for classes") were not included in the PISA 2003 questionnaire. Estimation of the PISA 2003 index treats these indices as missing and, under the assumption that the relationship between the items remains unchanged with the inclusion of the new questions, the PISA 2003 and PISA 2012 values on the index of teacher-related factors affecting school climate are comparable after the rescaling.

Student behaviour

The *index of student-related factors affecting school climate* (STUDCLIM) was derived from school principals' reports on the extent to which the learning of students was hindered by the following factors in their schools (SC22): *i*) student truancy; *ii*) students skipping classes; *iii*) students arriving late for school; *iv*) students not attending compulsory school events (e.g. sports day) or excursions; *v*) students lacking respect for teachers; *vi*) disruption of classes by students; *vii*) student use of alcohol or illegal drugs; and *viii*) students intimidating or bullying other students. As all items were inverted for scaling, higher values on this index indicate a positive student behaviour.

For trends analyses, the PISA 2003 values of the index of student-related factors affecting school climate were rescaled to be comparable to those in PISA 2012. As a result, values for the index of student-related factors affecting school climate for PISA 2003 reported in this volume may differ from those reported in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004). Two of the questions included to compute the index of student-related factors affecting school climate in PISA 2012 ("students arriving late for school," and "students not attending compulsory school events (e.g. sports day) or excursions") were not included in the PISA 2003 questionnaire. Estimation of the PISA 2003 index treats these questions as missing and, under the assumption that the relationship between the items remains unchanged with the inclusion of the new questions, the PISA 2003 and PISA 2012 values on the index of student-related factors affecting school climate are comparable after the rescaling.

Teacher morale

The *index of teacher morale* (TCMORALE) was derived from school principals' reports on the extent to which they agree with the following statements considering teachers in their schools (SC26): *i*) the morale of teachers in this school is high; *ii*) teachers work with enthusiasm; *iii*) teachers take pride in this school; and *iv*) teachers value academic achievement. As all items were inverted for scaling, higher values on this index indicate more positive teacher morale.

For trends analyses, the PISA 2003 values of the index of teacher morale were rescaled to be comparable to those in PISA 2012. As a result, values for the index teacher morale for PISA 2003 reported in this volume may differ from those reported in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004).

Questions used for the construction of the three opportunity to learn indices

Six questions were used from the Student Questionnaire to cover both the content and the time aspects of the opportunity to learn. These questions are shown below.

Question 1

How often have you encountered the following types of mathematics tasks during your time at school?

(Please tick only one box on each row.)

	Frequently	Sometimes	Rarely	Never
a) Working out from a <train timetable> how long it would take to get from one place to another.	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
b) Calculating how much more expensive a computer would be after adding tax.	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
c) Calculating how many square metres of tiles you need to cover a floor.	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
d) Understanding scientific tables presented in an article.	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
e) Solving an equation like: $6x^2 + 5 = 29$	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
f) Finding the actual distance between two places on a map with a 1:10,000 scale.	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
g) Solving an equation like $2(x+3) = (x+3)(x-3)$	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
h) Calculating the power consumption of an electronic appliance per week.	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
i) Solving an equation like: $3x+5=17$	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4

Question 2

Thinking about mathematical concepts: how familiar are you with the following terms?

(Please tick only one box in each row.)

	Never heard of it	Heard of it once or twice	Heard of it a few times	Heard of it often	Know it well, understand the concept
a) Exponential Function	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
b) Divisor	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
c) Quadratic Function	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
d) Linear Equation	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
e) Vectors	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
f) Complex Number	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
g) Rational Number	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
h) Radicals	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
i) Polygon	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
j) Congruent Figure	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
k) Cosine	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
l) Arithmetic Mean	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5
m) Probability	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4	<input type="checkbox"/> 5

The next four questions are about students' experience with different kinds of mathematics problems at school. They include some descriptions of problems and dark blue-coloured boxes, each containing a mathematics problem. The students had to read each problem but did not have to solve it.

Question 3

In the box is a series of problems. Each requires you to understand a problem written in text and perform the appropriate calculations. Usually the problem talks about practical situations, but the numbers and people and places mentioned are made up. All the information you need is given. Here are two examples:

1. <Ann> is two years older than <Betty> and <Betty> is four times as old as <Sam>. When <Betty> is 30, how old is <Sam>?
2. Mr <Smith> bought a television and a bed. The television cost <\$625> but he got a 10% discount. The bed cost <\$200>. He paid <\$20> for delivery. How much money did Mr <Smith> spend?

We want to know about your experience with these types of word problems at school. Do not solve them!

(Please tick only one box in each row.)

	Frequently	Sometimes	Rarely	Never
a) How often have you encountered these types of problems in your mathematics lessons ?	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
b) How often have you encountered these types of problems in the tests you have taken at school ?	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4

Question 4

Below are examples of another set of mathematical skills.

- 1) Solve $2x + 3 = 7$.
- 2) Find the volume of a box with sides 3m, 4m and 5m.

We want to know about your experience with these types of problems at school. Do not solve them!

(Please tick only one box in each row.)

	Frequently	Sometimes	Rarely	Never
a) How often have you encountered these types of problems in your mathematics lessons ?	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
b) How often have you encountered these types of problems in the tests you have taken at school ?	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4

Question 5

In the next type of problem, you have to use mathematical knowledge and draw conclusions. There is no practical application provided. Here are two examples.

- 1) Here you need to use geometrical theorems:

Determine the height of the pyramid.

- 2) Here you have to know what a prime number is:

If n is any number: can $(n+1)^2$ be a prime number?

We want to know about your experience with these types of problems at school. Do not solve them!

(Please tick only one box in each row.)

	Frequently	Sometimes	Rarely	Never
a) How often have you encountered these types of problems in your mathematics lessons ?	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
b) How often have you encountered these types of problems in the tests you have taken at school ?	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4

Question 6

In this type of problem, you have to apply suitable mathematical knowledge to find a useful answer to a problem that arises in everyday life or work. The data and information are about real situations. Here are two examples.

Example 1

A TV reporter says "This graph shows that there is a huge increase in the number of robberies from 1998 to 1999."

**Example 2**

For years the relationship between a person's recommended maximum heart rate and the person's age was described by the following formula:

$$\text{Recommended maximum heart rate} = 220 - \text{age}$$

Recent research showed that this formula should be modified slightly. The new formula is as follows:

$$\text{Recommended maximum heart rate} = 208 - (0.7 \times \text{age})$$

From which age onwards does the recommended maximum heart rate increase as a result of the introduction of the new formula? Show your work.

We want to know about your experience with these types of problems at school. Do not solve them!

(Please check only one box in each row.)

		Frequently	Sometimes	Rarely	Never
a)	How often have you encountered these types of problems in your mathematics lessons ?	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4
b)	How often have you encountered these types of problems in the tests you have taken at school ?	<input type="checkbox"/> 1	<input type="checkbox"/> 2	<input type="checkbox"/> 3	<input type="checkbox"/> 4

The three opportunity to learn indices

From these questions, three indices were constructed:

■ **The index of exposure to word problems**

This index was coded using the frequency choices for the word-problem type of task (Question 3) as follows:

frequently = 3, sometimes = 2, rarely = 1, and never = 0.

■ **The index of exposure to applied mathematics**

This index was constructed as the mean of the applied tasks involving both the mathematics contexts (Question 5) and the real-world contexts (Question 6). Each was separately scaled as:

frequently = 3, sometimes = 2, rarely = 1, and never = 0.

■ **The index of exposure to formal mathematics**

This index was created as the average of three scales.

- Two separate scales were constructed using the item asking for the degree of the student's familiarity with 7 of the 13 mathematics content areas (Question 2). The five response categories reflecting the degree to which they had heard of the topic were scaled 0 to 4 with 0 representing "never heard of it" 4 representing they "knew it well". The frequency codes for the three topics – exponential functions, quadratic functions, and linear equations – were averaged to define familiarity with algebra. Similarly, the average of four topics defined a geometry scale, including vectors, polygons, congruent figures, and cosines.
- The third scale was derived from the item where students indicated how often they had been confronted with problems defined as formal mathematics (Question 4). The frequency categories were coded as "frequently", "sometimes", and "rarely" equalling 1 and "never" equal to 0, resulting in a dichotomous variable. The algebra, geometry and formal mathematics tasks were averaged to form the index "formal mathematics", which ranged in values from 0 to 3, similar to the other three indices.

Notes

1. Note that for ISCO coding 0 “Arm forces”, the following recoding was followed: “Officers” were coded as “Managers” (ISCO 1), and “Other armed forces occupations” (drivers, gunners, seaman, generic armed forces) as “Plant and Machine operators” (ISCO 8). In addition, all answers starting with “97” (housewives, students, and “vague occupations”) were coded into missing.
2. The update from ISCO-88 to ISCO-08 mainly involved *i*) more adequate categories for IT-related occupations, *ii*) distinction of military ranks and *iii*) a revision of the categories classifying different managers
3. Information on ISCO08 and ISEI08 is included from <http://www.ilo.org/public/english/bureau/stat/isco/index.htm> and <http://home.fsw.vu.nl/hbg.ganzeboom/isco08>

ANNEX A2

THE PISA TARGET POPULATION, THE PISA SAMPLES AND THE DEFINITION OF SCHOOLS

Definition of the PISA target population

PISA 2012 provides an assessment of the cumulative yield of education and learning at a point at which most young adults are still enrolled in initial education.

A major challenge for an international survey is to ensure that international comparability of national target populations is guaranteed in such a venture.

Differences between countries in the nature and extent of pre-primary education and care, the age of entry into formal schooling and the institutional structure of education systems do not allow the definition of internationally comparable grade levels of schooling. Consequently, international comparisons of education performance typically define their populations with reference to a target age group. Some previous international assessments have defined their target population on the basis of the grade level that provides maximum coverage of a particular age cohort. A disadvantage of this approach is that slight variations in the age distribution of students across grade levels often lead to the selection of different target grades in different countries, or between education systems within countries, raising serious questions about the comparability of results across, and at times within, countries. In addition, because not all students of the desired age are usually represented in grade-based samples, there may be a more serious potential bias in the results if the unrepresented students are typically enrolled in the next higher grade in some countries and the next lower grade in others. This would exclude students with potentially higher levels of performance in the former countries and students with potentially lower levels of performance in the latter.

In order to address this problem, PISA uses an age-based definition for its target population, i.e. a definition that is not tied to the institutional structures of national education systems. PISA assesses students who were aged between 15 years and 3 (complete) months and 16 years and 2 (complete) months at the beginning of the assessment period, plus or minus a 1 month allowable variation, and who were enrolled in an educational institution with Grade 7 or higher, regardless of the grade levels or type of institution in which they were enrolled, and regardless of whether they were in full-time or part-time education. Educational institutions are generally referred to as schools in this publication, although some educational institutions (in particular, some types of vocational education establishments) may not be termed schools in certain countries. As expected from this definition, the average age of students across OECD countries was 15 years and 9 months. The range in country means was 2 months and 5 days (0.18 years), from the minimum country mean of 15 years and 8 months to the maximum country mean of 15 years and 10 months.

Given this definition of population, PISA makes statements about the knowledge and skills of a group of individuals who were born within a comparable reference period, but who may have undergone different educational experiences both in and outside of schools. In PISA, these knowledge and skills are referred to as the yield of education at an age that is common across countries. Depending on countries' policies on school entry, selection and promotion, these students may be distributed over a narrower or a wider range of grades across different education systems, tracks or streams. It is important to consider these differences when comparing PISA results across countries, as observed differences between students at age 15 may no longer appear as students' educational experiences converge later on.

If a country's scale scores in reading, scientific or mathematical literacy are significantly higher than those in another country, it cannot automatically be inferred that the schools or particular parts of the education system in the first country are more effective than those in the second. However, one can legitimately conclude that the cumulative impact of learning experiences in the first country, starting in early childhood and up to the age of 15, and embracing experiences both in school, home and beyond, have resulted in higher outcomes in the literacy domains that PISA measures.

The PISA target population did not include residents attending schools in a foreign country. It does, however, include foreign nationals attending schools in the country of assessment.

To accommodate countries that desired grade-based results for the purpose of national analyses, PISA 2012 provided a sampling option to supplement age-based sampling with grade-based sampling.

Population coverage

All countries attempted to maximise the coverage of 15-year-olds enrolled in education in their national samples, including students enrolled in special educational institutions. As a result, PISA 2012 reached standards of population coverage that are unprecedented in international surveys of this kind.

The sampling standards used in PISA permitted countries to exclude up to a total of 5% of the relevant population either by excluding schools or by excluding students within schools. All but eight countries, Luxembourg (8.34%), Canada (6.37%), Denmark (6.10%), Norway (6.09%), Estonia (5.67%), Sweden (5.42%), the United Kingdom (5.36%) and the United States (5.34%), achieved this standard, and in 30 countries and economies, the overall exclusion rate was less than 2%. When language exclusions were accounted for (i.e. removed from the overall exclusion rate), Norway, Sweden, the United Kingdom and the United States no longer had an exclusion rate greater than 5%. For details, see www.pisa.oecd.org.

Exclusions within the above limits include:

- At the school level: *i)* schools that were geographically inaccessible or where the administration of the PISA assessment was not considered feasible; and *ii)* schools that provided teaching only for students in the categories defined under “within-school exclusions”, such as schools for the blind. The percentage of 15-year-olds enrolled in such schools had to be less than 2.5% of the nationally desired target population [0.5% maximum for *i)* and 2% maximum for *ii)*]. The magnitude, nature and justification of school-level exclusions are documented in the *PISA 2012 Technical Report* (OECD, forthcoming).
- At the student level: *i)* students with an intellectual disability; *ii)* students with a functional disability; *iii)* students with limited assessment language proficiency; *iv)* other – a category defined by the national centres and approved by the international centre; and *v)* students taught in a language of instruction for the main domain for which no materials were available. Students could not be excluded solely because of low proficiency or common discipline problems. The percentage of 15-year-olds excluded within schools had to be less than 2.5% of the nationally desired target population.

Table A2.1 describes the target population of the countries participating in PISA 2012. Further information on the target population and the implementation of PISA sampling standards can be found in the *PISA 2012 Technical Report* (OECD, forthcoming).

- **Column 1** shows the *total number of 15-year-olds* according to the most recent available information, which in most countries meant the year 2011 as the year before the assessment.
- **Column 2** shows the number of 15-year-olds enrolled in schools in Grade 7 or above (as defined above), which is referred to as the *eligible population*.
- **Column 3** shows the *national desired target population*. Countries were allowed to exclude up to 0.5% of students a priori from the eligible population, essentially for practical reasons. The following a priori exclusions exceed this limit but were agreed with the PISA Consortium: Belgium excluded 0.23% of its population for a particular type of student educated while working; Canada excluded 1.14% of its population from Territories and Aboriginal reserves; Chile excluded 0.04% of its students who live in Easter Island, Juan Fernandez Archipelago and Antarctica; Indonesia excluded 1.55% of its students from two provinces because of operational reasons; Ireland excluded 0.05% of its students in three island schools off the west coast; Latvia excluded 0.08% of its students in distance learning schools; and Serbia excluded 2.11% of its students taught in Serbian in Kosovo.
- **Column 4** shows the *number of students enrolled in schools that were excluded from the national desired target population* either from the sampling frame or later in the field during data collection.
- **Column 5** shows the *size of the national desired target population after subtracting the students enrolled in excluded schools*. This is obtained by subtracting Column 4 from Column 3.
- **Column 6** shows the *percentage of students enrolled in excluded schools*. This is obtained by dividing Column 4 by Column 3 and multiplying by 100.
- **Column 7** shows the *number of students participating in PISA 2012*. Note that in some cases this number does not account for 15-year-olds assessed as part of additional national options.
- **Column 8** shows the *weighted number of participating students*, i.e. the number of students in the nationally defined target population that the PISA sample represents.
- Each country attempted to maximise the coverage of the PISA target population within the sampled schools. In the case of each sampled school, all eligible students, namely those 15 years of age, regardless of grade, were first listed. Sampled students who were to be excluded had still to be included in the sampling documentation, and a list drawn up stating the reason for their exclusion. **Column 9** indicates the *total number of excluded students*, which is further described and classified into specific categories in Table A2.2.
- **Column 10** indicates the *weighted number of excluded students*, i.e. the overall number of students in the nationally defined target population represented by the number of students excluded from the sample, which is also described and classified by exclusion categories in Table A2.2. Excluded students were excluded based on five categories: *i)* students with an intellectual disability – the student has a mental or emotional disability and is cognitively delayed such that he/she cannot perform in the PISA testing situation; *ii)* students with a functional disability – the student has a moderate to severe permanent physical disability such that he/she cannot perform in the PISA testing situation; *iii)* students with a limited assessment language proficiency – the student is unable to read or speak any of the languages of the assessment in the country and would be unable to overcome the language barrier in the testing situation (typically a student who has received less than one year of instruction in the languages of the assessment may be excluded); *iv)* other – a category defined by the national centres and approved by the international centre; and *v)* students taught in a language of instruction for the main domain for which no materials were available.
- **Column 11** shows the *percentage of students excluded within schools*. This is calculated as the weighted number of excluded students (Column 10), divided by the weighted number of excluded and participating students (Column 8 plus Column 10), then multiplied by 100.
- **Column 12** shows the *overall exclusion rate*, which represents the weighted percentage of the national desired target population excluded from PISA either through school-level exclusions or through the exclusion of students within schools. It is calculated as the school-level exclusion rate (Column 6 divided by 100) plus within-school exclusion rate (Column 11 divided by 100) multiplied by 1 minus the school-level exclusion rate (Column 6 divided by 100). This result is then multiplied by 100.

[Part 1/2]

Exclusion codes:

Code 1 Functional disability – student has a moderate to severe permanent physical disability.

Code 2 Intellectual disability – student has a mental or emotional disability and has either been tested as cognitively delayed or is considered in the professional opinion of qualified staff to be cognitively delayed.

Code 3 Limited assessment language proficiency – student is not a native speaker of any of the languages of the assessment in the country and has been resident in the country for less than one year.

Code 4 Other reasons defined by the national centres and approved by the international centre.

Code 5 No materials available in the language of instruction.

Note: For a full explanation of the details in this table please refer to the *PISA 2012 Technical Report* (OECD, forthcoming).

Information for the adjudicated regions is available on line.

* See notes at the beginning of this Annex.

StatLink  <http://dx.doi.org/10.1787/888932937092>

- **Column 13** presents an *index of the extent to which the national desired target population is covered by the PISA sample*. Canada, Denmark, Estonia, Luxembourg, Norway, Sweden, the United Kingdom and the United States were the only countries where the coverage is below 95%.
- **Column 14** presents an *index of the extent to which 15-year-olds enrolled in schools are covered by the PISA sample*. The index measures the overall proportion of the national enrolled population that is covered by the non-excluded portion of the student sample. The index takes into account both school-level and student-level exclusions. Values close to 100 indicate that the PISA sample represents the entire education system as defined for PISA 2012. The index is the weighted number of participating students (Column 8) divided by the weighted number of participating and excluded students (Column 8 plus Column 10), times the nationally defined target population (Column 5) divided by the eligible population (Column 2).
- **Column 15** presents an *index of the coverage of the 15-year-old population*. This index is the weighted number of participating students (Column 8) divided by the total population of 15-year-old students (Column 1).

This high level of coverage contributes to the comparability of the assessment results. For example, even assuming that the excluded students would have systematically scored worse than those who participated, and that this relationship is moderately strong, an exclusion rate in the order of 5% would likely lead to an overestimation of national mean scores of less than 5 score points (on a scale with an international mean of 500 score points and a standard deviation of 100 score points). This assessment is based on the following calculations: if the correlation between the propensity of exclusions and student performance is 0.3, resulting mean scores would likely be overestimated by 1 score point if the exclusion rate is 1%, by 3 score points if the exclusion rate is 5%, and by 6 score points if the exclusion rate is 10%. If the correlation between the propensity of exclusions and student performance is 0.5, resulting mean scores would be overestimated by 1 score point if the exclusion rate is 1%, by 5 score points if the exclusion rate is 5%, and by 10 score points if the exclusion rate is 10%. For this calculation, a model was employed that assumes a bivariate normal distribution for performance and the propensity to participate. For details, see the *PISA 2012 Technical Report* (OECD, forthcoming).

Sampling procedures and response rates

The accuracy of any survey results depends on the quality of the information on which national samples are based as well as on the sampling procedures. Quality standards, procedures, instruments and verification mechanisms were developed for PISA that ensured that national samples yielded comparable data and that the results could be compared with confidence.

Most PISA samples were designed as two-stage stratified samples (where countries applied different sampling designs, these are documented in the *PISA 2012 Technical Report* [OECD, forthcoming]). The first stage consisted of sampling individual schools in which 15-year-old students could be enrolled. Schools were sampled systematically with probabilities proportional to size, the measure of size being a function of the estimated number of eligible (15-year-old) students enrolled. A minimum of 150 schools were selected in each country (where this number existed), although the requirements for national analyses often required a somewhat larger sample. As the schools were sampled, replacement schools were simultaneously identified, in case a sampled school chose not to participate in PISA 2012.

In the case of Iceland, Liechtenstein, Luxembourg, Macao-China and Qatar, all schools and all eligible students within schools were included in the sample.

Experts from the PISA Consortium performed the sample selection process for most participating countries and monitored it closely in those countries that selected their own samples. The second stage of the selection process sampled students within sampled schools. Once schools were selected, a list of each sampled school's 15-year-old students was prepared. From this list, 35 students were then selected with equal probability (all 15-year-old students were selected if fewer than 35 were enrolled). The number of students to be sampled per school could deviate from 35, but could not be less than 20.

Data-quality standards in PISA required minimum participation rates for schools as well as for students. These standards were established to minimise the potential for response biases. In the case of countries meeting these standards, it was likely that any bias resulting from non-response would be negligible, i.e. typically smaller than the sampling error.

A minimum response rate of 85% was required for the schools initially selected. Where the initial response rate of schools was between 65% and 85%, however, an acceptable school response rate could still be achieved through the use of replacement schools. This procedure brought with it a risk of increased response bias. Participating countries were, therefore, encouraged to persuade as many of the schools in the original sample as possible to participate. Schools with a student participation rate between 25% and 50% were not regarded as participating schools, but data from these schools were included in the database and contributed to the various estimations. Data from schools with a student participation rate of less than 25% were excluded from the database.

PISA 2012 also required a minimum participation rate of 80% of students within participating schools. This minimum participation rate had to be met at the national level, not necessarily by each participating school. Follow-up sessions were required in schools in which too few students had participated in the original assessment sessions. Student participation rates were calculated over all original schools, and also over all schools, whether original sample or replacement schools, and from the participation of students in both the original assessment and any follow-up sessions. A student who participated in the original or follow-up cognitive sessions was regarded as a participant. Those who attended only the questionnaire session were included in the international database and contributed to the statistics presented in this publication if they provided at least a description of their father's or mother's occupation.

[Part 1/2]

Table A2.3 Response rates

		Initial sample – before school replacement					Final sample – after school replacement		
		Weighted school participation rate before replacement (%)	Weighted number of responding schools (weighted also by enrolment)	Weighted number of schools sampled (responding and non-responding) (weighted also by enrolment)	Number of responding schools (unweighted)	Number of responding and non-responding schools (unweighted)	Weighted school participation rate after replacement (%)	Weighted number of responding schools (weighted also by enrolment)	Weighted number of schools sampled (responding and non-responding) (weighted also by enrolment)

Table A2.3 shows the response rates for students and schools, before and after replacement.

- **Column 1** shows the *weighted participation rate of schools before replacement*. This is obtained by dividing Column 2 by Column 3, multiply by 100.
- **Column 2** shows the *weighted number of responding schools before school replacement* (weighted by student enrolment).
- **Column 3** shows the *weighted number of sampled schools before school replacement* (including both responding and non-responding schools, weighted by student enrolment).
- **Column 4** shows the *unweighted number of responding schools before school replacement*.
- **Column 5** shows the *unweighted number of responding and non-responding schools before school replacement*.
- **Column 6** shows the *weighted participation rate of schools after replacement*. This is obtained by dividing Column 7 by Column 8, multiply by 100.
- **Column 7** shows the *weighted number of responding schools after school replacement* (weighted by student enrolment).
- **Column 8** shows the *weighted number of schools sampled after school replacement* (including both responding and non-responding schools, weighted by student enrolment).
- **Column 9** shows the *unweighted number of responding schools after school replacement*.
- **Column 10** shows the *unweighted number of responding and non-responding schools after school replacement*.
- **Column 11** shows the *weighted student participation rate after replacement*. This is obtained by dividing Column 12 by Column 13, multiply by 100.
- **Column 12** shows the *weighted number of students assessed*.
- **Column 13** shows the *weighted number of students sampled* (including both students who were assessed and students who were absent on the day of the assessment).
- **Column 14** shows the *unweighted number of students assessed*. Note that any students in schools with student-response rates less than 50% were not included in these rates (both weighted and unweighted).
- **Column 15** shows the *unweighted number of students sampled* (including both students that were assessed and students who were absent on the day of the assessment). Note that any students in schools where fewer than half of the eligible students were assessed were not included in these rates (neither weighted nor unweighted).

Definition of schools

In some countries, sub-units within schools were sampled instead of schools and this may affect the estimation of the between-school variance components. In Austria, the Czech Republic, Germany, Hungary, Japan, Romania and Slovenia, schools with more than one study programme were split into the units delivering these programmes. In the Netherlands, for schools with both lower and upper secondary programmes, schools were split into units delivering each programme level. In the Flemish community of Belgium, in the case of multi-campus schools, implantations (campuses) were sampled, whereas in the French Community, in the case of multi-campus schools, the larger administrative units were sampled. In Australia, for schools with more than one campus, the individual campuses were listed for sampling. In Argentina, Croatia and Dubai (United Arab Emirates), schools that had more than one campus had the locations listed for sampling. In Spain, the schools in the Basque region with multi-linguistic models were split into linguistic models for sampling.

Grade levels

Students assessed in PISA 2012 are at various grade levels. The percentage of students at each grade level is presented by country and economy in Table A2.4a and by gender within each country and economy in Table A2.4b.

[Part 1/1]

Table A2.4a Percentage of students at each grade level

		Percentage of students at each grade level

ANNEX A3

TECHNICAL NOTES ON ANALYSES IN THIS VOLUME

Methods and definitions

Relative risk or increased likelihood

The relative risk is a measure of the association between an antecedent factor and an outcome factor. The relative risk is simply the ratio of two risks, i.e. the risk of observing the outcome when the antecedent is present and the risk of observing the outcome when the antecedent is not present. Figure A3.1 presents the notation that is used in the following.

■ Figure A3.1 ■

Labels used in a two-way table

P_{11}	P_{12}	$P_{1.}$
P_{21}	P_{22}	$P_{2.}$
$P_{.1}$	$P_{.2}$	$P_{..}$

$P_{..}$ is equal to $\frac{n_{..}}{n_{..}}$, with $n_{..}$ the total number of students and $P_{..}$ is therefore equal to 1, $P_{i.}$, $P_{.j}$ respectively represent the marginal probabilities for each row and for each column. The marginal probabilities are equal to the marginal frequencies divided by the total number of students. Finally, the P_{ij} represents the probabilities for each cell and are equal to the number of observations in a particular cell divided by the total number of observations.

In PISA, the rows represent the antecedent factor, with the first row for “having the antecedent” and the second row for “not having the antecedent”. The columns represent the outcome: the first column for “having the outcome” and the second column for “not having the outcome”. The relative risk is then equal to:

$$RR = \frac{(P_{11}/P_{1.})}{(P_{21}/P_{2.})}$$

Attributable risk or population relevance

The attributable risk, also referred to as population relevance in the text and tables of this volume, is interpreted as follows: if the risk factor could be eliminated, then the rate of occurrence of the outcome characteristic in the population would be reduced by this coefficient. The attributable risk is equal to (see Figure A3.1 for the notation that is used in the following formula):

$$AR = \frac{(P_{11}P_{22}) - (P_{12}P_{21})}{(P_{.1}P_{2.})}$$

The coefficients are multiplied by 100 to express the result as a percentage.

Statistics based on multilevel models

Statistics based on multi level models include variance components (between- and within-school variance), the index of inclusion derived from these components, and regression coefficients where this has been indicated. Multilevel models are generally specified as two-level regression models (the student and school levels), with normally distributed residuals, and estimated with maximum likelihood estimation. Where the dependent variable is mathematics performance, the estimation uses five plausible values for each student's performance on the mathematics scale. Models were estimated using Mplus® software.

In multilevel models, weights are used at both the student and school levels. The purpose of these weights is to account for differences in the probabilities of students being selected in the sample. Since PISA applies a two-stage sampling procedure, these differences are due to factors at both the school and the student levels. For the multilevel models, student final weights (W_FSTUWT) were used. Within-school-weights correspond to student final weights, rescaled to sum up within each school to the school sample size. Between-school weights correspond to the sum of student final weights (W_FSTUWT) within each school. The definition of between-school weights has changed with respect to PISA 2009.

The index of inclusion is defined and estimated as:

$$100 * \frac{\sigma_w^2}{\sigma_w^2 + \sigma_b^2}$$

where σ_w^2 and σ_b^2 , respectively, represent the within- and between-variance estimates.

The results in multilevel models, and the between-school variance estimate in particular, depend on how schools are defined and organised within countries and by the units that were chosen for sampling purposes. For example, in some countries, some of the schools in the PISA sample were defined as administrative units (even if they spanned several geographically separate institutions, as in Italy); in others they were defined as those parts of larger educational institutions that serve 15-year-olds; in still others they were defined as physical school buildings; and in others they were defined from a management perspective (e.g. entities having a principal). The *PISA 2012 Technical Report* (OECD, forthcoming) and Annex A2 provide an overview of how schools were defined. In Slovenia, the primary sampling unit is defined as a group of students who follow the same study programme within a school (an educational track within a school). So in this particular case the between-school variance is actually the within-school, between-track variation. The use of stratification variables in the selection of schools may also affect the estimate of the between-school variance, particularly if stratification variables are associated with between-school differences.

Because of the manner in which students were sampled, the within-school variation includes variation between classes as well as between students.

Multiple imputation replaces each missing value with a set of plausible values that represent the uncertainty about the right value to impute. The multiple imputed data sets are then analysed by using standard procedures for complete data and by combining results from these analyses. Five imputed values are computed for each missing value. Different methods can be used according to the pattern of missing values. For arbitrary missing data patterns, the MCMC (Monte Carlo Markov Chain) approach can be used.

This approach is used with the SAS procedure MI for the multilevel analyses in this volume. Multiple imputation is conducted separately for each model and each country, except for the model with all variables (Tables IV.1.12a, IV.1.12b and IV.1.12c) in which the data were constructed from imputed data for the individual models, such as the model for learning environment, model for selecting and grouping students, etc. Where continuous values are generated for missing discrete variables, these are rounded to the nearest discrete value of the variable. Each of the five plausible value of mathematics performance is analysed by Mplus® software using one of the five imputed data sets, which were combined taking account of the between imputation variance.

Standard errors and significance tests

The statistics in this report represent estimates of national performance based on samples of students, rather than values that could be calculated if every student in every country had answered every question. Consequently, it is important to measure the degree of uncertainty of the estimates. In PISA, each estimate has an associated degree of uncertainty, which is expressed through a standard error. The use of confidence intervals provides a way to make inferences about the population means and proportions in a manner that reflects the uncertainty associated with the sample estimates. From an observed sample statistic and assuming a normal distribution, it can be inferred that the corresponding population result would lie within the confidence interval in 95 out of 100 replications of the measurement on different samples drawn from the same population.

In many cases, readers are primarily interested in whether a given value in a particular country is different from a second value in the same or another country, e.g. whether girls in a country perform better than boys in the same country. In the tables and charts used in this report, differences are labelled as statistically significant when a difference of that size, smaller or larger, would be observed less than 5% of the time, if there were actually no difference in corresponding population values. Similarly, the risk of reporting a correlation as significant if there is, in fact, no correlation between two measures, is contained at 5%.

Throughout the report, significance tests were undertaken to assess the statistical significance of the comparisons made.

Gender differences and differences between subgroup means

Gender differences in student performance or other indices were tested for statistical significance. Positive differences indicate higher scores for boys while negative differences indicate higher scores for girls. Generally, differences marked in bold in the tables in this volume are statistically significant at the 95% confidence level.

Similarly, differences between other groups of students (e.g. native students and students with an immigrant background) were tested for statistical significance. The definitions of the subgroups can in general be found in the tables and the text accompanying the analysis. All differences marked in bold in the tables presented in Annex B of this report are statistically significant at the 95% level.

Differences between subgroup means, after accounting for other variables

For many tables, subgroup comparisons were performed both on the observed difference ("before accounting for other variables") and after accounting for other variables, such as the *PISA index of economic, social and cultural status of students* (ESCS). The adjusted differences were estimated using linear regression and tested for significance at the 95% confidence level. Significant differences are marked in bold.

Performance differences between the top and bottom quartiles of PISA indices and scales

Differences in average performance between the top and bottom quarters of the PISA indices and scales were tested for statistical significance. Figures marked in bold indicate that performance between the top and bottom quarters of students on the respective index is statistically significantly different at the 95% confidence level.

Differences between subgroups of schools

In this Volume, schools are compared across several aspects, such as resource allocation or performance. For this purpose, schools are grouped in categories by socio-economic status of students and schools, public-private status, lower and upper secondary education and school location. The differences between subgroups of schools are tested for statistical significance in the following way:

- *Socio-economic status of students*: Students in the top quarter of ESCS are compared to students in the bottom quarter of ESCS. If the difference is statistically significant at the 95% confidence levels, both figures are marked in bold. The second and third quarters do not enter the comparison.
- *Socio-economic status of schools*: advantaged schools are compared to disadvantaged schools. If the difference is statistically significant at the 95% confidence levels, both figures are marked in bold. Average schools do not enter the comparison.
- *Public and private schools*: Government-dependent and government-independent private schools are jointly considered as private schools. Figures in bold in data tables presented in Annex B of this report indicate statistically significant differences, at the 95% confidence level, between public and private schools.
- *Education levels*: Students at the upper secondary education are compared to students at the lower secondary education. If the difference is statistically significant at the 95% confidence levels, both figures are marked in bold.
- *School location*: For the purpose of significance tests, “schools located in a small town” and “schools located in a town” are jointly considered to form a single group. Figures for “schools located in a city or large city” are marked in bold in data tables presented in Annex B of this report if the difference with this middle category (“schools located in a small town” and “schools located in a town”) is significant at the 95% confidence levels. In turn, figures for “schools located in a village, hamlet, or rural area” are marked in bold if the difference with this middle category is significant. Differences between the extreme categories were not tested for significance.

Change in the performance per unit of the index

For many tables, the difference in student performance per unit of the index shown was calculated. Figures in bold indicate that the differences are statistically significantly different from zero at the 95% confidence level.

Relative risk or increased likelihood

Figures in bold in the data tables presented in Annex B of this report indicate that the relative risk is statistically significantly different from 1 at the 95% confidence level. To compute statistical significance around the value of 1 (the null hypothesis), the relative-risk statistic is assumed to follow a log-normal distribution, rather than a normal distribution, under the null hypothesis.

Attributable risk or population relevance

Figures in bold in the data tables presented in Annex B of this report indicate that the attributable risk is statistically significantly different from 0 at the 95% confidence level.

Standard errors in statistics estimated from multilevel models

For statistics based on multilevel models (such as the estimates of variance components and regression coefficients from two-level regression models) the standard errors are not estimated with the usual replication method which accounts for stratification and sampling rates from finite populations. Instead, standard errors are “model-based”: their computation assumes that schools, and students within schools, are sampled at random (with sampling probabilities reflected in school and student weights) from a theoretical, infinite population of schools and students which complies with the model’s parametric assumptions.

The standard error for the estimated index of inclusion is calculated by deriving an approximate distribution for it from the (model-based) standard errors for the variance components, using the delta-method.

Standard errors in trend analyses of performance: Link error

Standard errors for performance trend estimates had to be adjusted because the equating procedure that allows scores in different PISA assessments to be compared introduces a form of random error that is related to performance changes on the link items. These more conservative standard errors (larger than standard errors that were estimated before the introduction of the link error) reflect not only the measurement precision and sampling variation as for the usual PISA results, but also the link error (see Annex A5 for a technical discussion of the link error).

Link items represent only a subset of all items used to derive PISA scores. If different items were chosen to equate PISA scores over time, the comparison of performance for a group of students across time could vary. As a result, standard errors for the estimates of the change over time in mathematics, reading or science performance of a particular group (e.g. a country or economy, a region, boys, girls, students with an immigrant background, students without an immigrant background, socio-economically advantaged students, students in public schools, etc.) include the link error in addition to the sampling and imputation error commonly added to estimates in performance for a particular year. Because the equating procedure adds uncertainty to the position in the distribution (a change in the intercept) but does not result in any change in the variance of a distribution, standard errors for location-invariant estimates do not

include the link error. Location-invariant estimates include, for example, estimates for variances, regression coefficients for student- or school-level covariates, and correlation coefficients.

Figures in bold in the data tables for trends in performance presented in Annex B of this report indicate that the the change in performance for that particular group is statistically significantly different from 0 at the 95% confidence level. The standard errors used to calculate the statistical significance of the reported trend include the link error.

ANNEX A4

QUALITY ASSURANCE

Quality assurance procedures were implemented in all parts of PISA 2012, as was done for all previous PISA surveys.

The consistent quality and linguistic equivalence of the PISA 2012 assessment instruments were facilitated by providing countries with equivalent source versions of the assessment instruments in English and French and requiring countries (other than those assessing students in English and French) to prepare and consolidate two independent translations using both source versions. Precise translation and adaptation guidelines were supplied, also including instructions for selecting and training the translators. For each country, the translation and format of the assessment instruments (including test materials, marking guides, questionnaires and manuals) were verified by expert translators appointed by the PISA Consortium before they were used in the PISA 2012 Field Trial and Main Study. These translators' mother tongue was the language of instruction in the country concerned and they were knowledgeable about education systems. For further information on the PISA translation procedures, see the *PISA 2012 Technical Report* (OECD, forthcoming).

The survey was implemented through standardised procedures. The PISA Consortium provided comprehensive manuals that explained the implementation of the survey, including precise instructions for the work of School Co-ordinators and scripts for Test Administrators to use during the assessment sessions. Proposed adaptations to survey procedures, or proposed modifications to the assessment session script, were submitted to the PISA Consortium for approval prior to verification. The PISA Consortium then verified the national translation and adaptation of these manuals.

To establish the credibility of PISA as valid and unbiased and to encourage uniformity in administering the assessment sessions, Test Administrators in participating countries were selected using the following criteria: it was required that the Test Administrator not be the reading, mathematics or science instructor of any students in the sessions he or she would administer for PISA; it was recommended that the Test Administrator not be a member of the staff of any school where he or she would administer for PISA; and it was considered preferable that the Test Administrator not be a member of the staff of any school in the PISA sample. Participating countries organised an in-person training session for Test Administrators.

Participating countries and economies were required to ensure that: Test Administrators worked with the School Co-ordinator to prepare the assessment session, including updating student tracking forms and identifying excluded students; no extra time was given for the cognitive items (while it was permissible to give extra time for the student questionnaire); no instrument was administered before the two one-hour parts of the cognitive session; Test Administrators recorded the student participation status on the student tracking forms and filled in a Session Report Form; no cognitive instrument was permitted to be photocopied; no cognitive instrument could be viewed by school staff before the assessment session; and Test Administrators returned the material to the national centre immediately after the assessment sessions.

National Project Managers were encouraged to organise a follow-up session when more than 15% of the PISA sample was not able to attend the original assessment session.

National Quality Monitors from the PISA Consortium visited all national centres to review data-collection procedures. Finally, School Quality Monitors from the PISA Consortium visited a sample of seven schools during the assessment. For further information on the field operations, see the *PISA 2012 Technical Report* (OECD, forthcoming).

Marking procedures were designed to ensure consistent and accurate application of the marking guides outlined in the PISA Operations Manuals. National Project Managers were required to submit proposed modifications to these procedures to the Consortium for approval. Reliability studies to analyse the consistency of marking were implemented.

Software specially designed for PISA facilitated data entry, detected common errors during data entry, and facilitated the process of data cleaning. Training sessions familiarised National Project Managers with these procedures.

For a description of the quality assurance procedures applied in PISA and in the results, see the *PISA 2012 Technical Report* (OECD, forthcoming).

The results of adjudication showed that the PISA Technical Standards were fully met in all countries and economies that participated in PISA 2012, with the exception of Albania. Albania submitted parental occupation data that was incomplete and appeared inaccurate, since there was over-use of a narrow range of occupations. It was not possible to resolve these issues during the course of data cleaning, and as a result neither parental occupation data nor any indices which depend on this data are included in the international dataset. Results for Albania are omitted from any analyses which depend on these indices.

ANNEX A5

TECHNICAL DETAILS OF TRENDS ANALYSES

Comparing mathematics, reading and science performance across PISA cycles

The PISA 2003, 2006, 2009 and 2012 assessments use the same mathematics performance scale, which means that score points on this scale are directly comparable over time. The same is true for the reading performance scale used since PISA 2000 and the science performance scale used since PISA 2006. The comparability of scores across time is possible because of the use of link items that are common across assessments and can be used in the equating procedure to align performance scales. The items that are common across assessments are a subset of the total items that make up the assessment because PISA progressively renews its pool of items. As a result, out of a total of 110 items in the PISA 2012 mathematics assessment, 84 are linked to 2003 items, 48 to 2006 items and 35 to 2009 items. The number of PISA 2012 items linked to the PISA 2003 assessment is larger than the number linked to the PISA 2006 or the PISA 2009 assessments because mathematics was a major domain in PISA 2003 and PISA 2012. In PISA 2006 and PISA 2009, mathematics was a minor domain and all the mathematics items included in these assessments were link items. The *PISA 2012 Technical Report* (OECD, forthcoming) provides the technical details on equating the PISA 2012 mathematics scale for trends purposes.

Link error

Standard errors for performance trend estimates had to be adjusted because the equating procedure that allows scores in different PISA assessments to be compared introduces a form of random error that is related to performance changes on the link items. These more conservative standard errors (larger than standard errors that were estimated before the introduction of the link error) reflect not only the measurement precision and sampling variation as for the usual PISA results, but also the link error provided in Table A5.1.

Link items represent only a subset of all items used to derive PISA scores. If different items were chosen to equate PISA scores over time, the comparison of performance for a group of students across time could vary. As a result, standard errors for the estimates of the change over time in mathematics, reading or science performance of a particular group (e.g. a country or economy, a region, boys, girls, students with an immigrant background, students without an immigrant background, socio-economically advantaged students, students in public schools, etc.) include the link error in addition to the sampling and imputation error commonly added to estimates in performance for a particular year. Because the equating procedure adds uncertainty to the position in the distribution (a change in the intercept) but does not result in any change in the variance of a distribution, standard errors for location-invariant estimates do not include the link error. Location-invariant estimates include, for example, estimates for variances, regression coefficients for student- or school-level covariates, and correlation coefficients.

Link error for scores between two PISA assessments

The following equations describe how link errors between two PISA assessments are calculated. Suppose we have L score points in K units. Use i to index items in a unit and j to index units so that $\hat{\mu}_{ij}^y$ is the estimated difficulty of item i in unit j for year y , and let for example to compare PISA 2006 and PISA 2003:

$$c_{ij} = \hat{\mu}_{ij}^{2006} - \hat{\mu}_{ij}^{2003}$$

The size (total number of score points) of unit j is m_j so that:

$$\sum_{j=1}^K m_j = L$$

and

$$\bar{m} = \frac{1}{K} \sum_{j=1}^K m_j$$

Further let:

$$c_j = \frac{1}{m_j} \sum_{i=1}^{m_j} c_{ij}$$

and

$$\bar{c} = \frac{1}{N} \sum_{j=1}^K \sum_{i=1}^{m_j} c_{ij}$$

then the link error, taking clustering into account, is as follows:

$$error_{2006,2003} = \sqrt{\frac{\sum_{j=1}^K m_j^2 (c_j - \bar{c})^2}{K(K-1)\bar{m}^2}}$$

This approach for estimating the link errors was used in PISA 2006, PISA 2009 and PISA 2012. The link errors for comparisons of PISA 2012 results with previous assessments are shown in Table A5.1.

[Part 1/1]

Table A5.1 Link error for comparisons of performance between PISA 2012 and previous assessments

Comparison	Mathematics	Reading	Science
PISA 2000 to PISA 2012		5.923	
PISA 2003 to PISA 2012	1.931	5.604	
PISA 2006 to PISA 2012	2.084	5.580	3.512
PISA 2009 to PISA 2012	2.294	2.602	2.006

Note: Comparisons between PISA 2012 scores and previous assessments can only be made to when the subject first became a major domain. As a result, comparisons in mathematics performance between PISA 2012 and PISA 2000 are not possible, nor are comparisons in science performance between PISA 2012 and PISA 2000 or PISA 2003.

StatLink  <http://dx.doi.org/10.1787/888932937054>

Link error for other types of comparisons of student performance

The link error for other comparisons of performance does not have a straightforward theoretical solution as does the link error for comparison between two PISA assessments. The link error between two PISA assessments, described above, can be used, however, to empirically estimate the magnitude of the link error for the comparison of the percentage of students in a particular proficiency level or the magnitude of the link error associated with the estimation of the annualised and curvilinear change.

The empirical estimation of these link errors uses the assumption that the magnitude of the link error follows a normal distribution with mean 0 and a standard deviation equal to the link error shown in Table A5.1. From this distribution, 500 errors are drawn and added to the first plausible value for each assessment prior to 2012. The estimate of interest (change in the percentage of students in a particular proficiency level or the annualised change) is calculated for each of the 500 replicates. The standard deviation of these 500 estimates is then used as the link error for the annualised change, the quadratic change, and the change in the percentage of students scoring in a particular proficiency level. The values used to adjust standard errors in the calculation of the change in the percentage of students in each proficiency Level group are shown in Table A5.2 and those used for the adjustment of the linear and quadratic terms in the regressions models used to estimate the annualised change and the curvilinear change are shown in Table A5.3.

Comparisons of performance: Difference between two assessments and annualised change

To evaluate the evolution of performance, analyses report the change in performance between two cycles. Comparisons between two assessments (e.g. a country's/economy's change in performance between PISA 2003 and PISA 2012 or the change in performance of a subgroup) are calculated as:

$$\Delta_{2012-t} = PISA_{2012} - PISA_t$$

where Δ_{2012-t} is the difference in performance between PISA 2012 and a previous PISA assessment, where t can take any of the following values: 2000, 2003, 2006 or 2009. $PISA_{2012}$ is the mathematics, reading or science score observed in PISA 2012, and $PISA_t$ is the mathematics, reading or science score observed in a previous assessment (2000, 2003, 2006 or 2009). The standard error of the change in performance $\sigma(\Delta_{2012-t})$ is:

$$\sigma(\Delta_{2012-t}) = \sqrt{\sigma_{2012}^2 + \sigma_t^2 + error_{2012,t}^2}$$

where σ_{2012} is the standard error observed for $PISA_{2012}$, σ_t is the standard error observed for $PISA_t$ and $error_{2012,t}$ is the link error for comparisons of mathematics, reading or science performance between the PISA 2012 assessment and a previous (t) assessment. The value for $error_{2012,t}$ is shown in Table A5.1.

A second set of analyses reported in PISA relate to annualised changes in performance. The annualised change is the average annual rate of change observed through a country's/economy's participation in PISA. The annualised change is the average rate of change for a country's/economy's average mathematics, reading and science scores throughout their participation in PISA assessments. Thus, a positive annualised change of x points indicates that the country/economy has improved in performance by x points per year since its earliest comparable PISA results participated in PISA. For countries and economies that have participated in only two assessments, the annualised change is equal to the difference between the two assessments, divided by the number of years that passed between the assessments.

The annualised change in performance is calculated through an individual-level OLS regression of the form

$$PISA_i = \beta_0 + \beta_1 year_i + \varepsilon_i$$

where $PISA_i$ is student i 's mathematics, reading or science score, $year_i$ is the year student i took the PISA assessment and ε_i is an error term indicating student i 's difference from the group mean. Under this specification, the estimate for β_1 indicates the annualised rate of change. Just as a link error is added when drawing comparisons between two PISA assessments, the standard errors for β_1 also include a link error:

$$\sigma_{link}(\beta_1) = \sqrt{\sigma^2(\beta_1) + error_{annual}^2}$$

where $error_{annual}$ is the link error associated to the linear term in a regression model. It is presented in Table A5.3.

Note: The link error is calculated empirically by adding a random error component from a normal distribution with mean equal to zero and standard deviation equal to those shown in Table A5.1 to each student's scores in PISA 2000, PISA 2003, PISA 2006 or PISA 2009. Each country's percentage of students in each proficiency level band are then calculated for each of 500 replications. The standard deviation in the observed coefficients is the result of the added error and is the reported link error.

* United Arab Emirates excluding Dubai.

Note: The link error is calculated empirically by adding a random error component from a normal distribution with mean equal to zero and standard deviation equal to those shown in Table A5.1 to each student's scores in PISA 2000, PISA 2003, PISA 2006 or PISA 2009. Each country's percentage of students in each proficiency level band are then calculated for each of 500 replications. The standard deviation in the observed coefficients is the result of the added error and is the reported link error.

* United Arab Emirates excluding Dubai.

StatLink  <http://dx.doi.org/10.1787/888932937054>

The annualised change is a more robust measure of a country's/economy's progress in education outcomes as it is based on information available from all assessments. It is thus less sensitive to abnormal measurements that may alter a country's/economy's PISA trends if results are compared only between two assessments. The annualised change is calculated as the best-fitting line throughout a country's/economy's participation in PISA. The year that individual students participated in PISA is regressed on their PISA scores, yielding the annualised change. The annualised change also takes into account the fact that, for some countries and economies, the period between PISA assessments is less than three years. This is the case for those countries and economies that participated in PISA 2000 or PISA 2009 as part of PISA+: they conducted the assessment in 2001, 2002 or 2010 instead of 2000 or 2009. Figure A5.1 compares the value of the annualised change in mathematics with the difference in mathematics performance observed in PISA 2012 and PISA 2003.

■ Figure A5.1 ■

Annualised change in mathematics performance since PISA 2003 and observed differences in performance between PISA 2012 and PISA 2003

Note: The annualised change is the average annual change in PISA score points from a country's/economy's earliest participation in PISA to PISA 2012. It is calculated taking into account all country's/economy's participation in PISA.

StatLink <http://dx.doi.org/10.1787/888932937054>

Figures A5.2 and A5.3 do the same for reading and science: they compare the annualised change in performance with the difference between PISA 2012 and PISA 2000 and PISA 2006, respectively. In general, and especially in the comparison between science in PISA 2006 and PISA 2012, the annualised change provides a result similar to the difference in performance between two assessments. As more assessments are taken into account, the annualised change begins to differ from the observed trend, providing a more complete picture of a country's/economy's progress in PISA (in Figures A5.2 and A5.3).

Comparing items and non-performance scales across PISA cycles

To gather information about students' and schools' characteristics, PISA asks both students and schools to complete a background questionnaire. In PISA 2003 and PISA 2012 several questions were left untouched, allowing for a comparison of responses to these questions over time. In this report, only questions that retained the same wording were used for trends analyses. Questions with subtle word changes or questions with major word changes were not compared across time because it is impossible to discern whether observed changes in the response are due to changes in the construct they are measuring or to changes in the way the construct is being measured.

Also, as described in Annex A1, questionnaire items in PISA are used to construct indices. Whenever the questions used in the construction of indices remains intact in PISA 2003 and PISA 2012, the corresponding indices are compared. Two types of indices are used in PISA: simple indices and scale indices.

Simple indices recode a set of responses to questionnaire items. For trends analyses, the values observed in PISA 2003 are compared directly to PISA 2012, just as simple responses to questionnaire items are. This is the case of indices like student-teacher ratio and ability grouping in mathematics.

Scale indices, on the other hand, imply WLE estimates which require rescaling in order to be comparable across PISA cycles. Scale indices, like the *PISA index of economic, social and cultural status*, the *index of sense of belonging*, the *index of attitudes towards school*, the *index of intrinsic motivation to learn mathematics*, the *index of instrumental motivation to learn mathematics*, the *index of mathematics self-efficacy*, the *index of mathematics self-concept*, the *index of anxiety towards mathematics*, the *index of teacher shortage*, the *index of quality of physical infrastructure*, the *index of quality of educational resources*, the *index of disciplinary climate*, the *index of student-teacher relations*, the *index of teacher morale*, the *index of student-related factors affecting school climate*, and the *index of teacher-related factors affecting school climate*, were scaled in PISA 2012 to have an OECD mean of 0 and a standard deviation of 1. In PISA 2003 these same scales were scaled to have an OECD average of 0 and a standard deviation of 1. Because they are on different scales, values reported in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) cannot be compared with those reported in this volume. To make these scale indices comparable, values for 2003 have been rescaled to the 2012 scale, using the PISA 2012 parameter estimates.

To evaluate change in these items and scales, analyses report the change in the estimate between two assessments, usually PISA 2003 and PISA 2012. Comparisons between two assessments (e.g. a country's/economy's change index of anxiety towards mathematics between PISA 2003 and PISA 2012 or the change in this index for a subgroup) is calculated as:

$$\Delta_{2012,t} = PISA_{2012} - PISA_t$$

where $\Delta_{2012,t}$ is the difference in the index between PISA 2012 and a previous assessment, $PISA_{2012}$ is the index value observed in PISA 2012, and $PISA_t$ is the index value observed in a previous assessment (2000, 2003, 2006 or 2009). The standard error of the change in performance $\sigma(\Delta_{2012-t})$ is:

$$\sigma(\Delta_{2012-t}) = \sqrt{\sigma_{2012}^2 + \sigma_t^2}$$

where σ_{2012} is the standard error observed for $PISA_{2012}$ and σ_t is the standard error observed for $PISA_t$. These comparisons are based on an identical set of items; there is no uncertainty related to the choice of items for equating purposes, so no link error is needed.

Although only scale indices that use the same items in PISA 2003 and PISA 2012 are valid for trend comparisons, this does not imply that PISA 2012 indices that include exactly the same items as 2003 as well as new questionnaire items cannot be compared with PISA 2003 indices that included a smaller pool of items. In such cases, for example the *index of sense of belonging*, trend analyses were conducted by treating as missing in PISA 2003 items that were asked in the context of PISA 2012 but not in the PISA 2003 student questionnaire. This means that while the full set of information was used to scale the sense of belonging index in 2012, the PISA 2003 sense of belonging index was scaled under the assumption that if the 2012 items that were missing in 2003 had been asked in 2003, the overall index and index variation would have remained the same as those that were observed on common 2003 items. This is a tenable assumption inasmuch as in both PISA 2003 and PISA 2012 the questionnaire items used to construct the scale hold as an underlying factor in the construction of the scale.

OECD average

Throughout this report, the OECD average is used as a benchmark. It is calculated as the average across OECD countries, weighting each country equally. Some OECD countries did not participate in certain assessments, other OECD countries do not have comparable results for some assessments, others did not include certain questions in their questionnaires or changed them substantially from assessment to assessment. For this reason in trends tables and figures, the OECD average is reported as assessment-specific, that is, it includes only those countries for which there is comparable information in that particular assessment. This way, the 2003 OECD average includes only those OECD countries that have comparable information from the 2003 assessment, even if the results it refers to the PISA 2012 assessment and more countries have comparable information. This restriction allows for valid comparisons of the OECD average over time.

The reader should note that there are gaps in the numbering of tables because some tables appear on line only and are not included in this publication.

Notes regarding Cyprus

Note by Turkey: The information in this document with reference to “Cyprus” relates to the southern part of the Island. There is no single authority representing both Turkish and Greek Cypriot people on the Island. Turkey recognises the Turkish Republic of Northern Cyprus (TRNC). Until a lasting and equitable solution is found within the context of the United Nations, Turkey shall preserve its position concerning the “Cyprus issue”.

Note by all the European Union Member States of the OECD and the European Union: The Republic of Cyprus is recognised by all members of the United Nations with the exception of Turkey. The information in this document relates to the area under the effective control of the Government of the Republic of Cyprus.

A note regarding Israel

The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law.

Note: Values that are statistically significant are indicated in bold (see Annex A3). There are no direct comparisons with the OECD average in these tables.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Single-level bivariate regression of performance on the ESCS, the slope is the regression coefficient for ESCS.

3. Percentiles calculated at the student level.

4. Student-level regression of mathematics performance on the ESCS and the squared term of the ESCS; the index of curvilinearity is the regression coefficient for the squared term.

* See notes at the beginning of this Annex.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. The variable indicating the number of books available at home has been coded as: 0-10 books was coded as 5 books, 11-25 books as 18 books, 26-100 books as 63 books, 101-200 books as 150.5 books, 201-500 books as 350.5 books and more than 500 books as 750.5 books.

* See notes at the beginning of this Annex.

StatLink  <http://dx.doi.org/10.1787/888932964908>

[Part 5/7]

Elements of socio-economic status, by quarters of socio-economic status within countries
Results based on students' self-reports

Table II.2.2

		Cultural possessions: Percentage of students who reported that they have works of art at home								Cultural possessions: Percentage of students who reported that they have a desk for study at home

1. ESCS refers to the *PISA index of economic, social and cultural status*.

2. The variable indicating the number of books available at home has been coded as: 0-10 books was coded as 5 books, 11-25 books as 18 books, 26-100 books as 63 books, 101-200 books as 150.5 books, 201-500 books as 350.5 books and more than 500 books as 750.5 books.

* See notes at the beginning of this Annex.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. The variable indicating the number of books available at home has been coded as: 0-10 books was coded as 5 books, 11-25 books as 18 books, 26-100 books as 63 books, 101-200 books as 150.5 books, 201-500 books as 350.5 books and more than 500 books as 750.5 books.

* See notes at the beginning of this Annex.

[Part 1/2]
Elements of socio-economic status across countries
Results based on students' self-reports

Table II.2.3

			ESCS ¹		Highest parental education, in years		Highest parental education: Percentage of students with at least one parent whose educational attainment is...						Highest parental occupation: Percentage of students with at least one parent working in an occupation considered as...							
							No post-secondary education (ISCED 2 or less)		Upper secondary or post-secondary education (ISCED 3 and 4)		Tertiary education (ISCED 5 and 6)		Elementary (ISCO 9)		Semi-skilled blue-collar (ISCO 6, 7 and 8)		Semi-skilled white-collar (ISCO 4 and 5)		Skilled (ISCO 1, 2 and 3)	
			Mean index	S.E.	Mean years	S.E.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. The variable indicating the number of books available at home has been coded as follows: 0-10 books was coded as 5 books, 11-25 books as 18 books, 26-100 books as 63 books, 101-200 books as 150.5 books,

[Part 1/1]

Students' socio-economic status and mathematics performance

Table II.2.4a

By national quarters of the PISA index of economic, social and cultural status; results based on students' self-reports

		PISA index of economic, social and cultural status (ESCS)										Performance in mathematics, by national quarters of this index										Increased likelihood of students in the bottom quarter of the ESCS index scoring in the bottom quarter of the mathematics performance distribution	
		All students		Bottom quarter		Second quarter		Third quarter		Top quarter		Bottom quarter		Second quarter		Third quarter		Top quarter

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).StatLink  <http://dx.doi.org/10.1787/888932964908>

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).StatLink  <http://dx.doi.org/10.1787/888932964908>

[Part 3/3]

Change between 2003 and 2012 in students' socio-economic status and mathematics performance

Table II.2.4b

By national quarters of the PISA index of economic, social and cultural status; results based on students' self-reports

		Change between 2003 and 2012 (PISA 2012 - PISA 2003)																			
		PISA index of economic, social and cultural status (ESCS)										Performance in mathematics, by national quarters of this index								Increased likelihood of students in the bottom quarter of the ESCS index scoring in the bottom quarter of the mathematics performance distribution	
		All students		Bottom quarter		Second quarter		Third quarter		Top quarter		Bottom quarter		Second quarter		Third quarter		Top quarter

[Part 1/4]

Performance and selected elements of socio-economic status across countries

Table II.2.5 Results based on students' self-reports

		Parents' highest level of education																					
		Percentage of students whose parents have low (lower secondary at most: ISCED 2 or less) or high (tertiary or advanced research: ISCED 5 or 6) education				Mean performance of students whose parents' highest level of education is low (lower secondary at most: ISCED 2 or less) or high (tertiary or advanced research: ISCED 5 or 6)				Difference in performance between students with low- and high-educated parents		Increased likelihood of students whose parents have low levels of education scoring in the bottom quarter of the mathematics performance distribution		Population relevance of students whose parents have low levels of education scoring in the bottom quarter of the mathematics performance distribution		Increased likelihood of students whose parents have high levels of education scoring in the bottom quarter of the mathematics performance distribution		Population relevance of students whose parents have high levels of education scoring in the bottom quarter of the mathematics performance distribution		Effect size in mathematics performance for students whose parents have low levels of education		Effect size in mathematics performance for students whose parents have high levels of education

[Part 2/4]

Performance and selected elements of socio-economic status across countries
Results based on students' self-reports

Table II.2.5

		Parents' highest occupation																							
		Percentage of students whose parents' highest occupation is low- (elementary) or high- (professional, managerial) skilled				Mean performance of students whose parents' highest occupation is low- (elementary) or high- (professional, managerial) skilled				Difference in performance between students whose parents work in high- and low-skilled occupations Increased likelihood of students whose parents work in elementary occupations scoring in the bottom quarter of the mathematics performance distribution Population relevance of students whose parents work in elementary occupations scoring in the bottom quarter of the mathematics performance distribution Increased likelihood of students whose parents work in high-skilled occupations scoring in the bottom quarter of the mathematics performance distribution Population relevance of students whose parents work in high-skilled occupations scoring in the bottom quarter of the mathematics performance distribution Effect size in mathematics performance for students whose parents work in elementary occupations Effect size in mathematics performance for students whose parents work in high-skilled occupations

[Part 1/1]

Relationship between mathematics performance and elements of socio-economic status

Table II.2.6

Results based on students' self-reports

		Score-point difference in mathematics performance associated with each of the following factors, after accounting for the other factors												Explained variation in student performance (unique, ¹ common and total)									
		Intercept		Parents' highest occupational status		Parents' highest level of education		Index of cultural possessions		Index of home educational resources		Number of books at home		Wealth		Unique to:						Common explained variation (explained by more than one factor)	Total explained variation
		Mean score	S.E.	Score dif.	S.E.	Score dif.	S.E.	Score dif.	S.E.	Score dif.	S.E.	Score dif.	S.E.	%	%	%	%	%	%	%	%	%

Note: Values that are statistically significant are indicated in bold (see Annex A3).

1. A student is classified as resilient if he or she is in the bottom quarter of the *PISA index of economic, social and cultural status* (ESCS) in the country/economy of assessment and performs in the top quarter of students from all countries/economies, after accounting for socio-economic status.2. A student is classified as a disadvantaged low-achiever if he or she is in the bottom quarter of the *PISA index of economic, social and cultural status* (ESCS) in the country/economy of assessment and performs in the bottom quarter of students from all countries, after accounting for socio-economic status.

* See notes at the beginning of this Annex.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

Resiliency values for 2012 may differ from those shown in Table II.2.7a as the pooled reference population for resilient students used in this table is restricted to those countries and economies with comparable data from PISA 2003 and PISA 2012.

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

1. A student is classified as resilient if he or she is in the bottom quarter of the *PISA index of economic, social and cultural status* (ESCS) in the country/economy of assessment and performs in the top quarter of students from all countries/economies, after accounting for socio-economic status.StatLink  <http://dx.doi.org/10.1787/888932964908>

[Part 1/1]

Variation in mathematics performance

Results based on students' self-reports

Table II.2.8a

		Mean performance ¹		Total variation in mathematics performance ²		Variation in mathematics performance between schools ³		Variation in mathematics performance within schools ⁴		As a percentage of the average total variation in mathematics performance across OECD countries			Index of academic inclusion ⁵

1. The statistics computed for this table were estimated for all students, whether they had data on socio-economic status or not.

2. The total variation in student performance is calculated from the square of the standard deviation for all students.

3. In some countries, sub-units within schools were sampled instead of schools; this may affect the estimation of between-school variation components (see Annex A3).

4. Due to the unbalanced clustered nature of the data, the sum of the between- and within-school variation components, as an estimate from a sample, does not necessarily add up to the total.

5. The index of academic inclusion is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of performance, i.e. the variation in student performance between schools, divided by the sum of the variation in student performance between schools and the variation in student performance within schools.

* See notes at the beginning of this Annex.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

1. The statistics computed for this table were estimated for all students, whether they had data on socio-economic status or not.

2. The total variation in student performance is calculated from the square of the standard deviation for all students.

3. In some countries/economies, sub-units within schools were sampled instead of schools; this may affect the estimation of between-school variation components (see Annex A3).

4. Due to the unbalanced clustered nature of the data, the sum of the between- and within-school variation components, as an estimate from a sample, does not necessarily add up to the total.

5. The index of academic inclusion is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of performance, i.e. the variation in student performance between schools, divided by the sum of the variation in student performance between schools and the variation in student performance within schools.StatLink  <http://dx.doi.org/10.1787/888932964908>

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

1. In some countries, sub-units within schools were sampled instead of schools as administrative units; this may affect the estimation of school-level effects (see Annex A3).

2. ESCS refers to the *PISA index of economic, social and cultural status*.

3. Two-level regression of mathematics performance on student ESCS and school mean ESCS: within-school slope for ESCS and student-level variation explained by the model.

4. Two-level regression of mathematics performance on student ESCS and school mean ESCS: between-school slope for ESCS and school-level variation explained by the model.

5. Two-level regression of mathematics performance on student-level ESCS, student-level ESCS squared, school mean ESCS, and school mean ESCS squared. The within-school index of curvilinearity corresponds to the coefficient of student-level ESCS squared.

6. Two-level regression of mathematics performance on student ESCS, student ESCS squared, school mean ESCS and school mean ESCS squared: between-school index of curvilinearity corresponds to the coefficient of school mean ESCS squared.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

1. In some countries, sub-units within schools were sampled instead of schools as administrative units; this may affect the estimation of school-level effects (see Annex A3).

2. ESCS refers to the *PISA index of economic, social and cultural status*.

3. Two-level regression of mathematics performance on student ESCS and school mean ESCS: within-school slope for ESCS and student-level variation explained by the model.

4. Two-level regression of mathematics performance on student ESCS and school mean ESCS: between-school slope for ESCS and school-level variation explained by the model.

5. Two-level regression of mathematics performance on student-level ESCS, student-level ESCS squared, school mean ESCS, and school mean ESCS squared. The within-school index of curvilinearity corresponds to the coefficient of student-level ESCS squared.

6. Two-level regression of mathematics performance on student ESCS, student ESCS squared, school mean ESCS and school mean ESCS squared: between-school index of curvilinearity corresponds to the coefficient of school mean ESCS squared.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).1. ESCS refers to the *PISA index of economic, social and cultural status*.

2. Two-level regression of mathematics performance on student ESCS and school mean ESCS: within-school slope for ESCS and student-level variation explained by the model.

3. Two-level regression of mathematics performance on student ESCS and school mean ESCS: between-school slope for ESCS and school-level variation explained by the model.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).1. ESCS refers to the *PISA index of economic, social and cultural status*.

2. Two-level regression of mathematics performance on student ESCS and school mean ESCS: within-school slope for ESCS and student-level variation explained by the model.

3. Two-level regression of mathematics performance on student ESCS and school mean ESCS: between-school slope for ESCS and school-level variation explained by the model.

[Part 3/3]

Change between 2003 and 2012 in the relationship between mathematics performance and socio-economic status, between and within schools

Table II.2.9b Results based on students' self-reports

		Change between 2003 and 2012 (PISA 2012 - PISA 2003)											
		Overall association of ESCS and mathematics performance		Within-school association of ESCS and mathematics performance ²		Between-school association of ESCS and mathematics performance ³		Strength of the relationship between ESCS and mathematics performance		Within-school strength of the relationship between ESCS and mathematics performance ²		Between-school strength of the relationship between ESCS and mathematics performance ³	
		Change in the student-level score-point difference associated with one-unit increase in ESCS	S.E.	Change in the student-level score-point difference associated with one-unit increase in the student-level ESCS	S.E.	Change in the school-level score point-difference associated with one-unit increase in school mean ESCS	S.E.	Change in the percentage of the overall variation in student performance explained by students' socio-economic status	S.E.	Change in the percentage of the within-school variation in student performance explained by students' socio-economic status	S.E.	Change in the percentage of the between-school variation in student performance explained by schools' socio-economic status	S.E.

1. A socio-economically disadvantaged school is one whose students' mean socio-economic status is statistically significantly below the mean socio-economic status of the country; an average school is one where there is no difference between the students' and the country's mean socio-economic status; and an advantaged school is one whose students' mean socio-economic status is statistically significantly above the country's mean socio-economic status.

[Part 2/3]

Parents' education and occupation, and students' home possessions, by schools' socio-economic profile
Results based on students' self-reports

Table II.2.10

	Parents' highest occupation: Percentage of students with at least one parent working in an occupation considered as elementary (ISCO 9)						Parents' highest occupation: Percentage of students with at least one parent working in an occupation considered as semi-skilled blue-collar (ISCO 6, 7 and 8)						Parents' highest occupation: Percentage of students with at least one parent working in an occupation considered as semi-skilled white-collar (ISCO 4 and 5)

1. A socio-economically disadvantaged school is one whose students' mean socio-economic status is statistically significantly below the mean socio-economic status of the country; an average school is one where there is no difference between the students' and the country's mean socio-economic status; and an advantaged school is one whose students' mean socio-economic status is statistically significantly above the country's mean socio-economic status.

* See notes at the beginning of this Annex.

[Part 3/3]

Parents' education and occupation, and students' home possessions, by schools' socio-economic profile

Table II.2.10

Results based on students' self-reports

		Parents' highest occupation: Percentage of students with at least one parent working in an occupation considered as skilled (ISCO 1, 2 and 3)						Cultural possessions: Percentage of students who reported that they have poetry books at home						Number of books at home: Percentage of students who reported that they have at least 200 books at home

1. A socio-economically disadvantaged school is one whose students' mean socio-economic status is statistically significantly below the mean socio-economic status of the country/economy; an average school is one where there is no difference between the students' and the country's/economy's mean socio-economic status; and an advantaged school is one whose students' mean socio-economic status is statistically significantly above the country's/economy's mean socio-economic status. The classification by performance is done in an analogue way.

* See notes at the beginning of this Annex.

1. A socio-economically disadvantaged school is one whose students' mean socio-economic status is statistically significantly below the mean socio-economic status of the country/economy; an average school is one where there is no difference between the students' and the country's/economy's mean socio-economic status; and an advantaged school is one whose students' mean socio-economic status is statistically significantly above the country's/economy's mean socio-economic status. The classification by performance is done in an analogue way.

Note: These data come from Annex 2 in PISA 2003 and Annex A2 in this publication. If the proportion of students enrolled in grade 7 or above were higher than 100, then the figure for the total population of 15-year-olds was set to the proportion of 15-year-olds enrolled. These data are collected from different national data sources: for example, total population is collected from national censuses, which are conducted only in certain years. It is therefore possible that the population data are based on an older source than the enrolment data. These differences may result in an estimated enrolled population that is larger than the total population, which is clearly not possible.

* See notes at the beginning of this Annex.

Notes: These data come from Annex 2 in PISA 2003 and Annex A2 in this publication. If the proportion of students enrolled in grade 7 or above were higher than 100, then the figure for the total population of 15-year-olds was set to the proportion of 15-year-olds enrolled. These data are collected from different national data sources: for example, total population is collected from national censuses, which are conducted only in certain years. It is therefore possible that the population data are based on an older source than the enrolment data. These differences may result in an estimated enrolled population that is larger than the total population, which is clearly not possible.

* See notes at the beginning of this Annex.

1. Students with low ESCS are those with a value on the *PISA index of economic, social and cultural status* lower than -1.

2. Distribution of the school mean ESCS, percentiles calculated at the student level.

3. The *index of social inclusion* is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of socio-economic status, i.e. the between-school variation in the *PISA index of economic, social and cultural status* of students, divided by the sum of the between-school variation in students' socio-economic status and the within-school variation in students' socio-economic status.

* See notes at the beginning of this Annex.

1. Students with low ESCS are those with a value on the *PISA index of economic, social and cultural status* lower than -1.

2. Distribution of the school mean ESCS, percentiles calculated at the student level.

3. The *index of social inclusion* is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of socio-economic status, i.e. the between-school variation in the *PISA index of social, economic and cultural status* of students, divided by the sum of the between-school variation in students' socio-economic status and the within-school variation in students' socio-economic status.

* See notes at the beginning of this Annex.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).

1. ESCS refers to the *PISA index of economic, social and cultural status*.

2. Students with low ESCS are those with a value on the *PISA index of economic, social and cultural status* lower than -1.

3. The *index of social inclusion* is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of socio-economic status, i.e. the between-school variance in the *PISA index of social, economic and cultural status* of students, divided by the sum of the between-school variance in students' socio-economic status and the within-school variance in students' socio-economic status.

	Uruguay	-0.88	(0.03)	1.13	(0.02)	0.32	(0.03)	50.4	(1.1)	60.2	(3.5)

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).1. ESCS refers to the *PISA index of economic, social and cultural status*.2. Students with low ESCS are those with a value on the *PISA index of economic, social and cultural status* lower than -1.3. The *index of social inclusion* is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of socio-economic status, i.e. the between-school variance in the *PISA index of economic, social and cultural status* of students, divided by the sum of the between-school variance in students' socio-economic status and the within-school variance in students' socio-economic status.StatLink  <http://dx.doi.org/10.1787/888932964908>

[Part 3/3]

Change between 2003 and 2012 in the socio-economic status of students

Results based on students' self-reports

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details).

1. ESCS refers to the *PISA index of economic, social and cultural status*.

2. Students with low ESCS are those with a value on the *PISA index of economic, social and cultural status* lower than -1.

3. The *index of social inclusion* is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of socio-economic status, i.e. the between-school variance in the *PISA index of social, economic and cultural status* of students, divided by the sum of the between-school variance in students' socio-economic status and the within-school variance in students' socio-economic status.

[Part 2/2]

Mathematics performance and type of family

Table II.3.1

Results based on students' self-reports

		Difference in mathematics performance between students from single-parent families and those from other types of families, after accounting for ESCS		Difference in mathematics performance between students from single-parent families and those from other types of families, after accounting for ESCS		Increased likelihood of students from single-parent families scoring in the bottom quarter of the mathematics performance distribution		Population relevance of students from single-parent families scoring in the bottom quarter of the mathematics performance distribution		Effect size for students from single-parent families and other types of families in mathematics performance	
		Score dif.	S.E.	Score dif.	S.E.	Ratio	S.E.	%	S.E.	Effect size	S.E.

[Part 2/3]

Mathematics performance, parents' work status and socio-economic status
Results based on students' self-reports

Table II.3.2

		Mean mathematics performance										Difference in mathematics performance between students whose fathers are working and those whose fathers are not working		Difference in mathematics performance between students whose mothers are working and those whose mothers are not working		Difference in mathematics performance between students whose fathers are working and those whose fathers are not working, accounting for ESCS	
		Father's current job status				Mother's current job status											
		Working full- or part-time <for pay>		Not working, but looking for a job or having another status (e.g. home duties, retired)		Working full- or part-time <for pay>		Not working, but looking for a job or having another status (e.g. home duties, retired)

[Part 3/3]

Mathematics performance, parents' work status and socio-economic statusTable II.3.2 *Results based on students' self-reports*

	Difference in mathematics performance between students whose mothers are working and those whose mothers are not working, accounting for ESCS		Increased likelihood of students whose fathers are not working scoring in the bottom quarter of the mathematics performance distribution		Population relevance of students whose fathers are not working scoring in the bottom quarter of the mathematics performance distribution		Increased likelihood of students whose mothers are not working scoring in the bottom quarter of the mathematics performance distribution		Population relevance of students whose mothers are not working scoring in the bottom quarter of the mathematics performance distribution		Effect size in mathematics performance for students whose fathers are not working		Effect size in mathematics performance for students whose mothers are not working	
	Score dif.	S.E.	Ratio	S.E.	%	S.E.	Ratio	S.E.	%	S.E.	Effect size	S.E.	Effect size	S.E.

Viet Nam																		

Notes: This table was calculated considering only students with data on the PISA index of economic, social and cultural status. Values that are statistically significant are indicated in bold (see Annex A3).

* See notes at the beginning of this Annex.

StatLink  <http://dx.doi.org/10.1787/888932964927>

[Part 2/2]

Relationship between mathematics performance and school location*Results based on students' self-reports and school principals' reports*

Table II.3.3a

		Difference in mathematics score																	
		Average performance in mathematics after accounting for ESCS						BEFORE accounting for the PISA index of economic, social and cultural status of students (ESCS)						AFTER accounting for the PISA index of economic, social and cultural status of students (ESCS)					
		Students attending schools located in a village, hamlet or rural area (fewer than 3 000 people)		Students attending schools located in a town (3 000 to 100 000 people)		Students attending schools located in a city or large city (over 100 000 people)		Students in town schools compared with rural schools		Students in city schools compared with town schools		Students in city schools compared with rural schools		Students in town schools compared with rural schools		Students in city schools compared with town schools		Students in city schools compared with rural schools

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details). Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

1. ESCS refers to the *PISA index of economic, social and cultural status*.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details). Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

1. ESCS refers to the *PISA index of economic, social and cultural status*.

[Part 2/2]

Mathematics performance and immigrant background

Table II.3.4a

Results based on students' self-reports

	Difference in mathematics performance between non-immigrant and immigrant students AFTER accounting for socio-economic status		Increased likelihood of immigrant students scoring in the bottom quarter of the mathematics performance distribution		Population relevance of immigrant students scoring in the bottom quarter of the mathematics performance distribution		Effect size in mathematics performance for immigrant background (positive number implies an advantage for non-immigrant students)		Increased likelihood of non-immigrant students scoring in the bottom quarter of the mathematics performance distribution		Population relevance of non-immigrant students scoring in the bottom quarter of the mathematics performance distribution

Notes: This table was calculated considering only students with data on the PISA index of economic, social and cultural status. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are students whose parents were born in a country/economy other than the country/economy of assessment.

* See notes at the beginning of this Annex.

	Uruguay	99.2	(0.2)	0.8	(0.2)	423	(3.2)	424	(20.1)	-0.76	(0.04)	-0.39	(0.23)	-1	(19.3)	12	(19.5)

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are students whose parents were born in a country/economy other than the country/economy of assessment.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details). Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are students whose parents were born in a country/economy other than the country/economy of assessment.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details). Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3). The percentages of immigrant and non-immigrant students who speak the language of assessment at home and those who do not speak the language of assessment at home are calculated over the total student population. The percentages of first- and second-generation students who speak the language of assessment at home and those who do not speak the language of assessment at home are calculated over the total immigrant student population.

* See notes at the beginning of this Annex.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3). The percentages of immigrant and non-immigrant students who speak the language of assessment at home and those who do not speak the language of assessment at home are calculated over the total student population. The percentages of first- and second-generation students who speak the language of assessment at home and those who do not speak the language of assessment at home are calculated over the total immigrant student population.

* See notes at the beginning of this Annex.

StatLink  <http://dx.doi.org/10.1787/888932964927>

[Part 3/4]

Mathematics performance, immigrant background and language spoken at home
Results based on students' self-reports

Table II.3.5

		Performance differences after accounting for ESCS						Increased likelihood of non-immigrant students who speak the language of assessment at home scoring in the bottom quarter of the mathematics performance distribution		Population relevance of non-immigrant students who speak the language of assessment at home scoring in the bottom quarter of the mathematics performance distribution		Increased likelihood of non-immigrant students who do not speak the language of assessment at home scoring in the bottom quarter of the mathematics performance distribution		Population relevance of non-immigrant students who do not speak the language of assessment at home scoring in the bottom quarter of the mathematics performance distribution	
		Performance difference across non-immigrant students, by home language		Performance difference across immigrant students, by home language		Performance difference between immigrant students who do not speak the language of assessment at home and non-immigrant students who do

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3). The percentages of immigrant and non-immigrant students who speak the language of assessment at home and those who do not speak the language of assessment at home are calculated over the total student population. The percentages of first- and second-generation students who speak the language of assessment at home and those who do not speak the language of assessment at home are calculated over the total immigrant student population.

* See notes at the beginning of this Annex.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are those whose parents were born in a country/economy other than the country/economy of assessment. Second-generation immigrant students were born in the country/economy of assessment but their parents were not. First-generation immigrant students were not born in the country/economy of assessment and their parents were also not born in the country/economy of assessment.

* See notes at the beginning of this Annex.

[Part 2/3]

Mathematics performance and immigrant background for first- and second-generation students

Table II.3.6a

Results based on students' self-reports

	Difference in mathematics performance between non-immigrant and first-generation students		Difference in mathematics performance between non-immigrant and second-generation students		Difference in mathematics performance between second- and first-generation students		Difference in mathematics performance between non-immigrant and first-generation students, AFTER accounting for socio-economic status		Difference in mathematics performance between non-immigrant and second-generation students, AFTER accounting for socio-economic status		Difference in mathematics performance between second- and first-generation students, AFTER accounting for socio-economic status		Increased likelihood of first-generation students scoring in the bottom quarter of the mathematics performance distribution

Notes: This table was calculated considering only students with data on the PISA index of economic, social and cultural status. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are those whose parents were born in a country/economy other than the country/economy of assessment. Second-generation immigrant students were born in the country/economy of assessment but their parents were not. First-generation immigrant students were not born in the country/economy of assessment and their parents were also not born in the country/economy of assessment.

* See notes at the beginning of this Annex.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are those whose parents were born in a country/economy other than the country/economy of assessment. Second-generation immigrant students were born in the country/economy of assessment but their parents were not. First-generation immigrant students were not born in the country/economy of assessment and their parents were also not born in the country/economy of assessment.

* See notes at the beginning of this Annex.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are those whose parents were born in a country/economy other than the country/economy of assessment. Second-generation immigrant students were born in the country/economy of assessment but their parents were not. First-generation immigrant students were not born in the country/economy of assessment and their parents were also not born in the country/economy of assessment.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details). Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are those whose parents were born in a country/economy other than the country/economy of assessment. Second-generation immigrant students were born in the country/economy of assessment but their parents were not. First-generation immigrant students were not born in the country/economy of assessment and their parents were also not born in the country/economy of assessment.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details). Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are those whose parents were born in a country/economy other than the country/economy of assessment. Second-generation immigrant students were born in the country/economy of assessment but their parents were not. First-generation immigrant students were not born in the country/economy of assessment and their parents were also not born in the country/economy of assessment.

For comparability over time, PISA 2003 values on the *PISA index of economic, social and cultural status* have been rescaled to the PISA 2012 scale of the index. PISA 2003 results reported in this table may thus differ from those presented in *Learning for Tomorrow's World: First Results from PISA 2003* (OECD, 2004) (see Annex A5 for more details). Only countries and economies with comparable data from PISA 2003 and PISA 2012 are shown.

Notes: A student's country of origin is determined using both the country of birth the student reported for both their father and mother (only students with valid answers for both these variables are included in this analysis). Only students with an immigrant background (first- and second-generation students) are considered for this analysis. Only those students who reported a specific country of origin (that is, a country «other than the test country») were included in this analysis. If both parents share the same country of birth (different from the test country), then the student's country of origin is the same as his/her parents' country of birth. If they are different, then the father's country of birth is used.

* See notes at the beginning of this Annex.

Notes: A student's country of origin is determined using both the country of birth the student reported for both their father and mother (only students with valid answers for both these variables are included in this analysis). Only students with an immigrant background (first- and second-generation students) are considered for this analysis. Only those students who reported a specific country of origin (that is, a country «other than the test country») were included in this analysis. If both parents share the same country of birth (different from the test country), then the student's country of origin is the same as his/her parents' country of birth. If they are different, then the father's country of birth is used.

* See notes at the beginning of this Annex.

Note: Values that are statistically significant are indicated in bold (see Annex A3).

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Advantaged (disadvantaged) schools are those where the typical student in the school, or the socio-economic profile of the school, is above (below) the ESCS of the typical student in the country/economy, the country mean ESCS. In each school, a random sample of 35 students are to take part in PISA (for more details see PISA 2012 Technical Report, OECD, forthcoming). The socio-economic profile of the school is calculated using the information provided by these students. Therefore, the precision of the estimate depends on the number of students that actually take the test in the school and the diversity of their answers. This precision was taken into account when classifying schools as advantaged, disadvantaged or average. If the difference between the school socio-economic profile and the ESCS of the typical student in the country/economy (the mean ESCS at the country level) was not statistically significant, the school was classified as a school with an average socio-economic profile. If the school profile was statistically significantly above the country mean, the school is classified as a socio-economically advantaged school. If the profile was below the country mean, the school is classified as a socio-economically disadvantaged school.

* See notes at the beginning of this Annex.

Note: Values that are statistically significant are indicated in bold (see Annex A3).

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Advantaged (disadvantaged) schools are those where the typical student in the school, or the socio-economic profile of the school, is above (below) the ESCS of the typical student in the country/economy, the country mean ESCS. In each school, a random sample of 35 students are to take part in PISA (for more details see PISA 2012 Technical Report, OECD, forthcoming). The socio-economic profile of the school is calculated using the information provided by these students. Therefore, the precision of the estimate depends on the number of students that actually take the test in the school and the diversity of their answers. This precision was taken into account when classifying schools as advantaged, disadvantaged or average. If the difference between the school socio-economic profile and the ESCS of the typical student in the country/economy (the mean ESCS at the country level) was not statistically significant, the school was classified as a school with an average socio-economic profile. If the school profile was statistically significantly above the country mean, the school is classified as a socio-economically advantaged school. If the profile was below the country mean, the school is classified as a socio-economically disadvantaged school.

[Part 1/2]

Inequity in access to instructional content: Formal mathematics

Table II.4.3

Results based on students' self-reports

		Formal mathematics																					
		Percentage of the variation explained by student ESCS ¹		Percentage of the variation explained by student and school mean ESCS		Percentage of the variation explained by student and school mean and standard deviation of ESCS		Mean among students in socio-economically disadvantaged schools ² relative to the country mean ESCS		Mean among students in socio-economically average schools ² relative to the country mean ESCS		Mean among students in socio-economically advantaged schools ² relative to the country mean ESCS		Difference between students in disadvantaged and average schools		Difference between students in average and advantaged schools		Mean among non-immigrant students		Mean among immigrant students

[Part 1/1]

Correlation between student performance and selected student and school characteristics

Results based on students' self-reports

Table II.4.4

		Study behaviour				Student and teacher profile				School climate					
		Attendance in after-school lessons		Homework or other study set by your teachers		Student-teacher ratio		Composition and qualifications of mathematics teaching staff		Student-related factors affecting school climate		Behavioural outcomes: Dropout		Parental pressure to achieve

[Part 1/1]

Correlation of the variation of students' socio-economic status within a school and selected student and school characteristics

Results based on students' self-reports

Table II.4.7

		Study behaviour				Student and teacher profile				School climate					
		Attendance in after-school lessons		Homework or other study set by your teachers		Student-teacher ratio		Composition and qualifications of mathematics teaching staff		Student-related factors affecting school climate		Behavioural outcomes: Dropout		Parental pressure to achieve

[Part 1/2]

Inequity in access to educational resources: Student-teacher ratio

Table II.4.8

Results based on students' self-reports

		Student-teacher ratio																			
		Percentage of the variation explained by student ESCS ¹		Percentage of the variation explained by student and school mean ESCS		Percentage of the variation explained by student and school mean and standard deviation of ESCS		Mean among students in socio-economically disadvantaged schools, ² relative to the country mean ESCS		Mean among students in socio-economically average schools, ² relative to the country mean ESCS		Mean among students in socio-economically advantaged schools, ² relative to the country mean ESCS		Difference between students in average and disadvantaged schools		Difference between students in advantaged and average schools		Difference between students in disadvantaged and advantaged schools		Mean among non-immigrant students

Note: Values that are statistically significant are indicated in bold (see Annex A3).

1. ESCS refers to the PISA index of economic, social and cultural status.

2. A socio-economically disadvantaged school is one whose students' mean ESCS is statistically significantly below the mean ESCS of the country/economy; an average school is one where there is no difference between the students' and the country's mean ESCS; and an advantaged school is one whose students' mean ESCS is statistically significantly above the country mean.

* See notes at the beginning of this Annex.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

All the models presented here include student- and school-level socio-economic status. Then individual characteristics (gender, immigrant background and language at home) and school location are included. All of these variables are kept for each model. School- and student-level variables measuring availability and quality of resources are introduced one group at a time. At the end, all variables are combined in a single model: The "combined model". Some students, schools and countries do not have data for some of these variables, therefore they are not included in the combined model. Then a baseline model, with only student- and school-level socio-economic status is presented, where all students, schools and countries without data have been omitted, which allows for a more direct comparison with the estimates in the combined model.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Parental pressure to achieve is based on the school-level index (PARPRES).

3. School climate includes the following variables: xdisclim (aggregated to the school level from the student questionnaire), studclim and teacclim, both school-level indices measuring student and teacher factors related to school disciplinary climate.

4. Opportunity to learn includes the following variables: index of exposure to formal mathematics, index to exposure to word problems, index of exposure to applied mathematics (the simple index and the index squared), all of these indices.

5. Opportunity to learn at the school level includes all of the same opportunity-to-learn indices at both the student and the school levels (except applied mathematics squared).

6. Teacher profile includes the following variables: student-teacher ratio, composition and qualifications of mathematics teaching staff, proportion of certified teachers and teacher shortage.

7. School educational resources and physical infrastructure include: shortage of educational physical infrastructure and shortage of educational resources in school.

8. School proportion of early school-leavers includes: behavioural outcomes – dropout.

* See notes at the beginning of this Annex.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

All the models presented here include student- and school-level socio-economic status. Then individual characteristics (gender, immigrant background and language at home) and school location are included. All of these variables are kept for each model. School- and student-level variables measuring availability and quality of resources are introduced one group at a time. At the end, all variables are kept in a single model: The "combined model". Some students, schools and countries do not have data for some of these variables, therefore they are not included in the combined model. Then a baseline model, with only student- and school-level socio-economic status is presented, where all students, schools and countries without data have been omitted, which allows for a more direct comparison with the estimates in the combined model.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Parental pressure to achieve is based on the school-level index (PARPRES).

3. School climate includes the following variables: xdisclim (aggregated to the school level from the student questionnaire), studclim and teacclim, both school-level indices measuring student and teacher factors related to school disciplinary climate.

4. Opportunity to learn includes the following variables: index of exposure to formal mathematics, index of exposure to word problems, index of exposure to applied mathematics (the simple index and the index squared), all of these indices.

5. Opportunity to learn at the school level includes all of the same opportunity-to-learn indices at both the student and the school levels (except applied mathematics squared).

6. Teacher profile includes the following variables: student-teacher ratio, composition and qualifications of mathematics teaching staff, proportion of certified teachers and teacher shortage.

7. School educational resources and physical infrastructure include: shortage of educational physical infrastructure and shortage of educational resources in school.

8. School proportion of early school-leavers includes: behavioural outcomes – dropout.

* See notes at the beginning of this Annex.

Viet Nam	37	(13.9)	9	(5.9)	4	(6.1)

Note: Values that are statistically significant are indicated in bold (see Annex A3).

1. Mathematics performance is regressed on the following variables: student had attended pre-primary school; student's socio-economic status; (student had attended pre-primary school)*(student's socio-economic status); a square of student's socio-economic status; school's socio-economic profile; gender; student with an immigrant background; school in rural area; school in a city; school size; a square of school size; and private school.

2. Socio-economically advantaged students correspond to students with a PISA index of economic, social and cultural status that is one unit higher than the OECD average.

* See notes at the beginning of this Annex.

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3). There are no direct comparison with the OECD average in these tables.

See Table II.2.1 for national data.

1. ESCS refers to the *PISA index of economic, social and cultural status*.

2. Single-level bivariate regression of performance on ESCS, the slope is the regression coefficient for ESCS.

3. Percentiles calculated at the student level.

4. Student-level regression of mathematics performance on the ESCS index and the squared term of the ESCS, the index of curvilinearity is the regression coefficient for the squared term.

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3). There are no direct comparison with the OECD average in these tables.

See Table II.2.1 for national data.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Single-level bivariate regression of performance on ESCS, the slope is the regression coefficient for ESCS.

3. Percentiles calculated at the student level.

4. Student-level regression of mathematics performance on the ESCS index and the squared term of the ESCS, the index of curvilinearity is the regression coefficient for the squared term.

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

1. ESCS refers to the PISA index of economic, social and cultural status.

See Table II.2.4a for national data.

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

See Table II.2.7a for national data.

1. A student is classified as resilient if he or she is in the bottom quarter of the *PISA index of economic, social and cultural status* (ESCS) in the country of assessment and performs in the top quarter of students from all countries, after accounting for socio-economic status.2. A student is classified as disadvantaged low-achiever, if he or she is in the bottom quarter of the *PISA index of economic, social and cultural status* (ESCS) in the country of assessment and performs in the bottom quarter of students from all countries, after accounting for socio-economic background.StatLink  <http://dx.doi.org/10.1787/888932964965>

[Part 2/2]

Percentage of resilient students and low-achievers among disadvantaged students in PISA 2012, by gender and region

Table B2.II.4 Results based on students' self-reports

		Resilient and disadvantaged low-achievers																
		Resilient students ¹						Disadvantaged low-achievers ²										
		All students		Boys		Girls		Difference (boys - girls)		All students		Boys		Girls		Difference (boys - girls)		
		%	S.E.	%	S.E.	%	S.E.	% dif.	S.E.	%	S.E.	%	S.E.	%	S.E.	% dif.	S.E.

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

See Table II.2.7a for national data.

1. A student is classified as resilient if he or she is in the bottom quarter of the *PISA index of economic, social and cultural status* (ESCS) in the country of assessment and performs in the top quarter of students from all countries, after accounting for socio-economic status.2. A student is classified as disadvantaged low-achiever, if he or she is in the bottom quarter of the *PISA index of economic, social and cultural status* (ESCS) in the country of assessment and performs in the bottom quarter of students from all countries, after accounting for socio-economic background.StatLink  <http://dx.doi.org/10.1787/888932964965>

* PISA adjudicated region.

Note: See Table II.2.8a for national data.

1. The statistics computed for this table were estimated for all students, whether they had data on socio-economic status or not.

2. The total variation in student performance is calculated from the square of the standard deviation for all students.

3. In some countries, sub-units within schools were sampled instead of schools; this may affect the estimation of between-school variance components (see Annex A3).

4. Due to the unbalanced clustered nature of the data, the sum of the between- and within-school variation components, as an estimate from a sample, does not necessarily add up to the total.

5. The index of academic inclusion is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of performance, i.e. the variation in student performance between schools, divided by the sum of the variation in student performance between schools and the variation in student performance within schools.StatLink  <http://dx.doi.org/10.1787/888932964965>

* PISA adjudicated region.

Note: See Table II.2.8a for national data.

1. The statistics computed for this table were estimated for all students, whether they had data on socio-economic status or not.

2. The total variation in student performance is calculated from the square of the standard deviation for all students.

3. In some countries, sub-units within schools were sampled instead of schools; this may affect the estimation of between-school variance components (see Annex A3).

4. Due to the unbalanced clustered nature of the data, the sum of the between- and within-school variation components, as an estimate from a sample, does not necessarily add up to the total.

5. The index of academic inclusion is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of performance, i.e. the variation in student performance between schools, divided by the sum of the variation in student performance between schools and the variation in student performance within schools.StatLink  <http://dx.doi.org/10.1787/888932964965>

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

See Table II.2.9a for national data.

1. In some countries, sub-units within schools were sampled instead of schools as administrative units; this may affect the estimation of school-level effects (see Annex A3).

2. ESCS refers to the *PISA index of economic, social and cultural status*.

3. Two-level regression of mathematics performance on student ESCS and school mean ESCS: within-school slope for ESCS and student-level variation explained by the model.

4. Two-level regression of mathematics performance on student ESCS and school mean ESCS: between-school slope for ESCS and school-level variation explained by the model.

5. Two-level regression of mathematics performance on student-level ESCS, student-level ESCS squared, school mean ESCS, and school mean ESCS squared. The within-school index of curvilinearity corresponds to the coefficient of student-level ESCS squared.

6. Two-level regression of mathematics performance on student ESCS, student ESCS squared, school mean ESCS and school mean ESCS squared: between-school index of curvilinearity corresponds to the coefficient of school mean ESCS squared.

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

See Table II.2.9a for national data.

1. In some countries, sub-units within schools were sampled instead of schools as administrative units; this may affect the estimation of school-level effects (see Annex A3).

2. ESCS refers to the PISA index of economic, social and cultural status.

3. Two-level regression of mathematics performance on student ESCS and school mean ESCS: within-school slope for ESCS and student-level variation explained by the model.

4. Two-level regression of mathematics performance on student ESCS and school mean ESCS: between-school slope for ESCS and school-level variation explained by the model.

5. Two-level regression of mathematics performance on student-level ESCS, student-level ESCS squared, school mean ESCS, and school mean ESCS squared. The within-school index of curvilinearity corresponds to the coefficient of student-level ESCS squared.

6. Two-level regression of mathematics performance on student ESCS, student ESCS squared, school mean ESCS and school mean ESCS squared: between-school index of curvilinearity corresponds to the coefficient of school mean ESCS squared.

3. Two-level regression of mathematics performance on student ESCS and school mean ESCS: within-school slope for ESCS and student-level variation explained by the model.

4. Two-level regression of mathematics performance on student ESCS and school mean ESCS: between-school slope for ESCS and school-level variation explained by the model.

5. Two-level regression of mathematics performance on student-level ESCS, student-level ESCS squared, school mean ESCS, and school mean ESCS squared. The within-school index of curvilinearity corresponds to the coefficient of student-level ESCS squared.

6. Two-level regression of mathematics performance on student ESCS, student ESCS squared, school mean ESCS and school mean ESCS squared: between-school index of curvilinearity corresponds to the coefficient of school mean ESCS squared.

* PISA adjudicated region.

Note: See Table II.2.13a for national data.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Students with low ESCS are those with a value on the PISA index of economic, social and cultural status lower than -1.

3. Distribution of the school mean ESCS, percentiles calculated at the student level.

4. The index of social inclusion is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of socio-economic status, i.e. the between-school variation in the PISA index of social, economic and cultural status of students, divided by the sum of the between-school variation in students' socio-economic status and the within-school variation in students' socio-economic status.

* PISA adjudicated region.

Note: See Table II.2.13a for national data.

1. ESCS refers to the *PISA index of economic, social and cultural status*.2. Students with low ESCS are those with a value on the *PISA index of economic, social and cultural status* lower than -1.

3. Distribution of the school mean ESCS, percentiles calculated at the student level.

4. The *index of social inclusion* is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of socio-economic status, i.e. the between-school variation in the *PISA index of social, economic and cultural status* of students, divided by the sum of the between-school variation in students' socio-economic status and the within-school variation in students' socio-economic status.StatLink  <http://dx.doi.org/10.1787/888932964965>

[Part 4/4]

The socio-economic background of students in PISA 2012, by region

Table B2.II.7 Results based on students' self-reports

		Variation in distribution of students across ESCS						Variation in distribution of schools across ESCS ³						Index of social inclusion ⁴	
		25th percentile of ESCS		75th percentile of ESCS		Interquartile range of distribution of students across ESCS		25th percentile of school mean ESCS		75th percentile of school mean ESCS		Interquartile range of distribution of schools across ESCS

* PISA adjudicated region.

Note: See Table II.2.13a for national data.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Students with low ESCS are those with a value on the PISA index of economic, social and cultural status lower than -1.

3. Distribution of the school mean ESCS, percentiles calculated at the student level.

4. The index of social inclusion is calculated as $100 \times (1 - \rho)$, where ρ stands for the intra-class correlation of socio-economic status, i.e. the between-school variation in the PISA index of social, economic and cultural status of students, divided by the sum of the between-school variation in students' socio-economic status and the within-school variation in students' socio-economic status.StatLink  <http://dx.doi.org/10.1787/888932964965>

[Part 1/4]

Mathematics performance and immigrant background, by region**Table B2.II.9** *Results based on students' self-reports*

		Percentage of students				ESCS ¹				Mathematics performance			
		Non-immigrant		Immigrant		Non-immigrant		Immigrant		Non-immigrant		Immigrant

* PISA adjudicated region.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are students whose parents were born in a country other than the country of assessment.

See Table II.3.4a for national data.

1. ESCS refers to the *PISA index of economic, social and cultural status*.StatLink  <http://dx.doi.org/10.1787/888932964965>

[Part 3/4]

Mathematics performance and immigrant background, by region**Table B2.II.9** *Results based on students' self-reports*

	Difference in mathematics performance between non-immigrant and immigrant students		Difference in mathematics performance between non-immigrant and immigrant students AFTER accounting for ESCS		Increased likelihood of immigrant students scoring in the bottom quarter of the mathematics performance distribution		Population relevance of immigrant students scoring in the bottom quarter of the mathematics performance distribution		Effect size for immigrant background in mathematics performance (positive number implies an advantage for non-immigrant students)		Increased likelihood of non-immigrant students scoring in the bottom quarter of the mathematics performance distribution		Population relevance of non-immigrant students scoring in the bottom quarter of the mathematics performance distribution

* PISA adjudicated region.

Notes: This table was calculated considering only students with data on the *PISA index of economic, social and cultural status*. Values that are statistically significant are indicated in bold (see Annex A3).

Students with an immigrant background are students whose parents were born in a country other than the country of assessment.

See Table II.3.4a for national data.

1. ESCS refers to the *PISA index of economic, social and cultural status*.StatLink  <http://dx.doi.org/10.1787/888932964965>

[Part 4/4]

Mathematics performance and immigrant background, by region

Table B2.II.9 Results based on students' self-reports

	Difference in mathematics performance between non-immigrant and immigrant students		Difference in mathematics performance between non-immigrant and immigrant students AFTER accounting for ESCS		Increased likelihood of immigrant students scoring in the bottom quarter of the mathematics performance distribution		Population relevance of immigrant students scoring in the bottom quarter of the mathematics performance distribution		Effect size for immigrant background in mathematics performance (positive number implies an advantage for non-immigrant students)		Increased likelihood of non-immigrant students scoring in the bottom quarter of the mathematics performance distribution		Population relevance of non-immigrant students scoring in the bottom quarter of the mathematics performance distribution

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

See Table II.4.2 for national data.

1. ESCS refers to the *PISA index of economic, social and cultural status*.

2. Advantaged (disadvantaged) schools are those where the typical student in the school, or the socio-economic profile of the school, is above (below) the ESCS of the typical student in the country, the country mean ESCS. In each school, a random sample of 35 students are to take part in PISA (for more details see *PISA 2012 Technical Report* [OECD, forthcoming]). The socio-economic profile of the school is calculated using the information provided by these students. Therefore, the precision of the estimate depends on the number of students that actually take the test in the school and the diversity of their answers. This precision was taken into account when classifying schools as advantaged, disadvantaged or average. If the difference between the school socio-economic profile and the ESCS of the typical student in the country (the mean ESCS at the country level) was not statistically significant, the school was classified as a school with an average socio-economic profile. If the school profile was statistically significantly above the country mean, the school is classified as a socio-economically advantaged school. If the profile was below the country mean, the school is classified as a socio-economically disadvantaged school.

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

See Table II.4.2 for national data.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Advantaged (disadvantaged) schools are those where the typical student in the school, or the socio-economic profile of the school, is above (below) the ESCS of the typical student in the country, the country mean ESCS. In each school, a random sample of 35 students are to take part in PISA (for more details see PISA 2012 Technical Report [OECD, forthcoming]). The socio-economic profile of the school is calculated using the information provided by these students. Therefore, the precision of the estimate depends on the number of students that actually take the test in the school and the diversity of their answers. This precision was taken into account when classifying schools as advantaged, disadvantaged or average. If the difference between the school socio-economic profile and the ESCS of the typical student in the country (the mean ESCS at the country level) was not statistically significant, the school was classified as a school with an average socio-economic profile. If the school profile was statistically significantly above the country mean, the school is classified as a socio-economically advantaged school. If the profile was below the country mean, the school is classified as a socio-economically disadvantaged school.

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

See Table II.4.2 for national data.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Advantaged (disadvantaged) schools are those where the typical student in the school, or the socio-economic profile of the school, is above (below) the ESCS of the typical student in the country, the country mean ESCS. In each school, a random sample of 35 students are to take part in PISA (for more details see PISA 2012 Technical Report [OECD, forthcoming]). The socio-economic profile of the school is calculated using the information provided by these students. Therefore, the precision of the estimate depends on the number of students that actually take the test in the school and the diversity of their answers. This precision was taken into account when classifying schools as advantaged, disadvantaged or average. If the difference between the school socio-economic profile and the ESCS of the typical student in the country (the mean ESCS at the country level) was not statistically significant, the school was classified as a school with an average socio-economic profile. If the school profile was statistically significantly above the country mean, the school is classified as a socio-economically advantaged school. If the profile was below the country mean, the school is classified as a socio-economically disadvantaged school.

* PISA adjudicated region.

Notes: Values that are statistically significant are indicated in bold (see Annex A3).

See Table II.4.2 for national data.

1. ESCS refers to the PISA index of economic, social and cultural status.

2. Advantaged (disadvantaged) schools are those where the typical student in the school, or the socio-economic profile of the school, is above (below) the ESCS of the typical student in the country, the country mean ESCS. In each school, a random sample of 35 students are to take part in PISA (for more details see PISA 2012 Technical Report [OECD, forthcoming]). The socio-economic profile of the school is calculated using the information provided by these students. Therefore, the precision of the estimate depends on the number of students that actually take the test in the school and the diversity of their answers. This precision was taken into account when classifying schools as advantaged, disadvantaged or average. If the difference between the school socio-economic profile and the ESCS of the typical student in the country (the mean ESCS at the country level) was not statistically significant, the school was classified as a school with an average socio-economic profile. If the school profile was statistically significantly above the country mean, the school is classified as a socio-economically advantaged school. If the profile was below the country mean, the school is classified as a socio-economically disadvantaged school.

Inequity in access to instructional content: Formal mathematics, by region

Table B2.II.16 Results based on students' self-reports

		Formal mathematics																			
		Difference between non-immigrant and immigrant students		Mean among students who speak the language of assessment at home		Mean among students who do not speak the language of assessment at home		Difference between students who speak the language of assessment at home and those who do not		Mean among students in rural schools		Mean among students in town schools (small town and town)		Mean among students in urban schools (city and large city)		Difference between students in rural and town schools		Difference between students in town and urban schools		Difference between students in rural and urban schools

* PISA adjudicated region.

Notes: For students in socio-economically average and advantaged schools, values that are statistically significant different from those for students in disadvantaged schools are indicated in bold (see Annex A3).

See Table II.4.3 for

[Part 1/6]

Pre-primary school attendance, mathematics performance and students' socio-economic status, by region

Table B2.II.24 Results based on students' self-reports

		Results based on students' self-reports												Average mathematics performance of students with							
		Percentage of students with						Mean ESCS ¹													
		No pre-primary school attendance		Pre-primary school attendance for one year or less		Pre-primary school attendance for more than one year		No pre-primary school attendance		Pre-primary school attendance for one year or less		Pre-primary school attendance for more than one year

* PISA adjudicated region.

Notes: This table was calculated considering only students with data on the PISA index of economic, social and cultural status. Values that are statistically significant are indicated in bold (see Annex A3).

See Table II.4.12 for national data.

1. ESCS refers to the PISA index of economic, social and cultural status.

StatLink  <http://dx.doi.org/10.1787/888932964965>

[Part 3/6]

Pre-primary school attendance, mathematics performance and students' socio-economic status, by region

Table B2.II.24 Results based on students' self-reports

	Difference in mathematics performance between students who reported having attended pre-primary school for one year or less and those who had not attended pre-primary school				Difference in mathematics performance between students who reported having attended pre-primary school for more than one year and those who had not attended pre-primary school				Increased likelihood of students who had not attended pre-primary school scoring in the bottom quarter of the national mathematics performance distribution		Population relevance of students who had not attended pre-primary school scoring in the bottom quarter of the national mathematics performance distribution

Annex C

THE DEVELOPMENT AND IMPLEMENTATION OF PISA – A COLLABORATIVE EFFORT

PISA is a collaborative effort, bringing together experts from the participating countries, steered jointly by their governments on the basis of shared, policy-driven interests.

A PISA Governing Board, on which each country is represented, determines the policy priorities for PISA, in the context of OECD objectives, and oversees adherence to these priorities during the implementation of the programme. This includes setting priorities for the development of indicators, for establishing the assessment instruments, and for reporting the results.

Experts from participating countries also serve on working groups that are charged with linking policy objectives with the best internationally available technical expertise. By participating in these expert groups, countries ensure that the instruments are internationally valid and take into account the cultural and educational contexts in OECD member and partner countries and economies, that the assessment materials have strong measurement properties, and that the instruments place emphasis on authenticity and educational validity.

Through National Project Managers, participating countries and economies implement PISA at the national level subject to the agreed administration procedures. National Project Managers play a vital role in ensuring that the implementation of the survey is of high quality, and verify and evaluate the survey results, analyses, reports and publications.

The design and implementation of the surveys, within the framework established by the PISA Governing Board, is the responsibility of external contractors. For PISA 2012, the development and implementation of the cognitive assessment and questionnaires, and of the international options, was carried out by a consortium led by the Australian Council for Educational Research (ACER). Other partners in this Consortium include cApStAn Linguistic Quality Control in Belgium, the Centre de Recherche Public Henri Tudor (CRP-HT) in Luxembourg, the Department of Teacher Education and School Research (ILS) at the University of Oslo in Norway, the Deutsches Institut für Internationale Pädagogische Forschung (DIPF) in Germany, the Educational Testing Service (ETS) in the United States, the Leibniz Institute for Science and Mathematics Education (IPN) in Germany, the National Institute for Educational Policy Research in Japan (NIER), the Unité d'analyse des systèmes et des pratiques d'enseignement (aSPe) at the University of Liège in Belgium, and WESTAT in the United States, as well as individual consultants from several countries. ACER also collaborated with Achieve, Inc. in the United States to develop the mathematics framework for PISA 2012.

The OECD Secretariat has overall managerial responsibility for the programme, monitors its implementation daily, acts as the secretariat for the PISA Governing Board, builds consensus among countries and serves as the interlocutor between the PISA Governing Board and the international Consortium charged with implementing the activities. The OECD Secretariat also produces the indicators and analyses and prepares the international reports and publications in co-operation with the PISA Consortium and in close consultation with member and partner countries and economies both at the policy level (PISA Governing Board) and at the level of implementation (National Project Managers).

PISA Governing Board

Chair of the PISA Governing Board: Lorna Bertrand

OECD countries

Australia: Tony Zanderigo

Austria: Mark Németh

Belgium: Christiane Blondin and Isabelle Erauw

Canada: Pierre Brochu, Patrick Bussiere and Tomasz Gluszynski

Chile: Leonor Cariola Huerta

Czech Republic: Jana Paleckova

Denmark: Tine Bak and Elsebeth Aller

Estonia: Maie Kitsing

Finland: Tommi Karjalainen

France: Bruno Trosseille

Germany: Elfriede Ohrnberger and Susanne von Below

Greece: Vassilia Hatzinikita and Chryssa Sofianopoulou

Hungary: Benő Csapó

Iceland: Júlíus Björnsson

Ireland: Jude Cosgrove and Gerry Shiel

Israel: Michal Beller and Hagit Glickman

Italy: Paolo Sestito

Japan: Ryo Watanabe

Korea: Sungsook Kim and Keunwoo Lee

Luxembourg: Amina Kafai

Mexico: Francisco Ciscomani and Eduardo Backhoff Escudero

Netherlands: Paul van Oijen

New Zealand: Lynne Whitney

Norway: Anne-Berit Kavli and Alette Schreiner

Poland: Stanislaw Drzazdzewski and Hania Bouacid

Portugal: Luisa Canto and Castro Loura

Slovak Republic: Romana Kanovska and Paulina Korsnakova

Slovenia: Andreja Barle Lakota

Spain: Ismael Sanz Labrador

Sweden: Anita Wester

Switzerland: Vera Husfeldt and Claudia Zahner Rossier

Turkey: Nurcan Devici and Mustafa Nadir Çalis

United Kingdom: Lorna Bertrand and Jonathan Wright

United States: Jack Buckley, Dana Kelly and Daniel McGrath

Observers

Albania: Ermal Elezi

Argentina: Liliana Pascual

Brazil: Luiz Claudio Costa

Bulgaria: Neda Kristanova

Chinese Taipei: Gwo-Dong Chen and Chih-Wei Hue

Colombia: Adriana Molina

Costa Rica: Leonardo Garnier Rimolo

Croatia: Michelle Bras Roth

Hong Kong-China: Esther Sui-chu Ho
Indonesia: Khairil Anwar Notodiputro
Jordan: Khattab Mohammad Abulibdeh
Kazakhstan: Almagul Kultumanova
Latvia: Andris Kangro, Ennata Kivrina and Dita Traidis
Lithuania: Rita Dukynaite
Macao-China: Leong Lai
Montenegro: Zeljko Jacimovic
Panama: Arturo Rivera
Peru: Liliana Miranda Molina
Qatar: Hamda Al Sulaiti
Romania: Roxana Mihail
Russian Federation: Isak Froumin and Galina Kovaleva
Serbia: Dragica Pavlovic-Babic
Shanghai-China: Minxuan Zhang
Singapore: Khah Gek Low
Thailand: Precharn Dechsri
United Arab Emirates: Moza al Ghufly and Ayesha G. Khalfan Almerri
Uruguay: Andrés Peri and Maria Helvecia Sanchez Nunez
Viet Nam: Le Thi My Ha

PISA 2012 National Project Managers

Albania: Alfonso Harizaj
Argentina: Liliana Pascual
Australia: Sue Thomson
Austria: Ursula Schwantner
Belgium: Inge De Meyer and Ariane Baye
Brazil: João Galvão Bacchetto
Bulgaria: Svetla Petrova
Canada: Pierre Brochu and Tamara Knighton
Chile: Ema Lagos Campos
Colombia: Francisco Reyes
Costa Rica: Lilliam Mora
Croatia: Michelle Bras Roth
Czech Republic: Jana Paleckova
Denmark: Niels Egelund
Estonia: Gunda Tire
Finland: Jouni Välijärvi
France: Ginette Bourny
Germany: Christine Sälzer and Manfred Prenzel
Greece: Vassilia Hatzinikita
Hong Kong-China: Esther Sui-chu Ho
Hungary: Ildikó Balazsi
Iceland: Almar Midvik Halldorsson
Indonesia: Yulia Wardhani Nugaan and Hari Setiadi
Ireland: Gerry Shiel and Rachel Perkins
Israel: Joel Rapp and Inbal Ron-Kaplan
Italy: Carlo Di Chiacchio
Japan: Ryo Watanabe
Jordan: Khattab Mohammad Abulibdeh
Kazakhstan: Gulmira Berdibayeva and Zhannur Azmagambetova

Korea: Ji-Min Cho and Mi-Young Song
Latvia: Andris Kangro
Liechtenstein: Christian Nidegger
Lithuania: Mindaugas Stundza
Luxembourg: Bettina Boehm
Macao-China: Kwok Cheung Cheung
Malaysia: Ihsan Ismail and Muhamad Zaini Md Zain
Mexico: María Antonieta Díaz Gutierrez

ORGANISATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT

The OECD is a unique forum where governments work together to address the economic, social and environmental challenges of globalisation. The OECD is also at the forefront of efforts to understand and to help governments respond to new developments and concerns, such as corporate governance, the information economy and the challenges of an ageing population. The Organisation provides a setting where governments can compare policy experiences, seek answers to common problems, identify good practice and work to co-ordinate domestic and international policies.

The OECD member countries are: Australia, Austria, Belgium, Canada, Chile, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Israel, Italy, Japan, Korea, Luxembourg, Mexico, the Netherlands, New Zealand, Norway, Poland, Portugal, the Slovak Republic, Slovenia, Spain, Sweden, Switzerland, Turkey, the United Kingdom and the United States. The European Union takes part in the work of the OECD.

OECD Publishing disseminates widely the results of the Organisation's statistics gathering and research on economic, social and environmental issues, as well as the conventions, guidelines and standards agreed by its members.

PISA 2012 Results: Excellence through Equity

GIVING EVERY STUDENT THE CHANCE TO SUCCEED

VOLUME II

The OECD Programme for International Student Assessment (PISA) examines not just what students know in mathematics, reading and science, but what they can do with what they know. This is one of six volumes that present the results of the 2012 PISA survey, the fifth round of the triennial assessment.

Volume I, *What Students Know and Can Do: Student Performance in Mathematics, Reading and Science*, summarises the performance of students in PISA 2012.

Volume II, *Excellence through Equity: Giving Every Student the Chance to Succeed*, defines and measures equity in education and analyses how equity in education has evolved across countries between PISA 2003 and 2012.

Volume III, *Ready to Learn: Students' Engagement, Drive and Self-Beliefs*, explores students' engagement with and at school, their drive and motivation to succeed, and the beliefs they hold about themselves as mathematics learners.

Volume IV, *What Makes Schools Successful? Resources, Policies and Practices*, examines how student performance is associated with various characteristics of individual schools and school systems.

Volume V, *Skills for Life: Student Performance in Problem Solving*, presents student performance in the PISA 2012 assessment of problem solving, which measures students' capacity to respond to non-routine situations.

Volume VI, *Students and Money: Financial Literacy Skills for the 21st Century*, examines students' experience with and knowledge about money.

Contents of this volume

- Chapter 1. Defining and measuring equity in education
- Chapter 2. Equity in outcomes
- Chapter 3. The challenge of diversity
- Chapter 4. Equity in opportunities to learn and in resources
- Chapter 5. Policy implications of equity in education
